---

THIS volume forms the twenty-first of a series, composed of original memoirs on different branches of knowledge, published at the expense, and under the direction, of the Smithsonian Institution. The publication of this series forms part of a general plan adopted for carrying into effect the benevolent intentions of JAMES SMITHSON, Esq., of England. This gentleman left his property in trust to the United States of America, to found, at Washington, an institution which should bear his own name, and have for its objects the “*increase and diffusion* of knowledge among men.” This trust was accepted by the Government of the United States, and an Act of Congress was passed August 10, 1846, constituting the President and the other principal executive officers of the general government, the Chief Justice of the Supreme Court, the Mayor of Washington,<sup>1</sup> and such other persons as they might elect honorary members, an establishment under the name of the “SMITHSONIAN INSTITUTION FOR THE INCREASE AND DIFFUSION OF KNOWLEDGE AMONG MEN.” The members and honorary members of this establishment are to hold stated and special meetings for the supervision of the affairs of the Institution, and for the advice and instruction of a Board of Regents, to whom the financial and other affairs are intrusted.

The Board of Regents consists of two members *ex officio* of the establishment, namely, the Vice-President of the United States and the Chief Justice of the Supreme Court, together with twelve other members, three of whom are appointed by the Senate from its own body, three by the House of Representatives from its members, and six persons appointed by a joint resolution of both houses. To this Board is given the power of electing a Secretary and other officers, for conducting the active operations of the Institution.

To carry into effect the purposes of the testator, the plan of organization should evidently embrace two objects: one, the increase of knowledge by the addition of new truths to the existing stock; the other, the diffusion of knowledge, thus increased, among men. No restriction is made in favor of any kind of knowledge; and, hence, each branch is entitled to, and should receive, a share of attention.

---

<sup>1</sup> This office has been abolished.

The Act of Congress, establishing the Institution, directs, as a part of the plan of organization, the formation of a Library, a Museum, and a Gallery of Art, together with provisions for physical research and popular lectures, while it leaves to the Regents the power of adopting such other parts of an organization as they may deem best suited to promote the objects of the bequest.

After much deliberation, the Regents resolved to divide the annual income into two parts—one part to be devoted to the increase and diffusion of knowledge by means of original research and publications—the other part of the income to be applied in accordance with the requirements of the Act of Congress, to the gradual formation of a Library, a Museum, and a Gallery of Art.

The following are the details of the parts of the general plan of organization provisionally adopted at the meeting of the Regents, Dec. 8, 1847.

#### DETAILS OF THE FIRST PART OF THE PLAN.

I. TO INCREASE KNOWLEDGE.—*It is proposed to stimulate research, by offering rewards for original memoirs on all subjects of investigation.*

1. The memoirs thus obtained, to be published in a series of volumes, in a quarto form, and entitled "Smithsonian Contributions to Knowledge."

2. No memoir, on subjects of physical science, to be accepted for publication, which does not furnish a positive addition to human knowledge, resting on original research; and all unverified speculations to be rejected.

3. Each memoir presented to the Institution, to be submitted for examination to a commission of persons of reputation for learning in the branch to which the memoir pertains; and to be accepted for publication only in case the report of this commission is favorable.

4. The commission to be chosen by the officers of the Institution, and the name of the author, as far as practicable, concealed, unless a favorable decision be made.

5. The volumes of the memoirs to be exchanged for the Transactions of literary and scientific societies, and copies to be given to all the colleges, and principal libraries, in this country. One part of the remaining copies may be offered for sale; and the other carefully preserved, to form complete sets of the work, to supply the demand from new institutions.

6. An abstract, or popular account, of the contents of these memoirs to be given to the public, through the annual report of the Regents to Congress.

II. TO INCREASE KNOWLEDGE.—*It is also proposed to appropriate a portion of the income, annually, to special objects of research, under the direction of suitable persons.*

1. The objects, and the amount appropriated, to be recommended by counsellors of the Institution.

2. Appropriations in different years to different objects; so that, in course of time, each branch of knowledge may receive a share.

3. The results obtained from these appropriations to be published, with the memoirs before mentioned, in the volumes of the Smithsonian Contributions to Knowledge.

4. Examples of objects for which appropriations may be made:—

(1.) System of extended meteorological observations for solving the problem of American storms.

(2.) Explorations in descriptive natural history, and geological, mathematical, and topographical surveys, to collect material for the formation of a Physical Atlas of the United States.

(3.) Solution of experimental problems, such as a new determination of the weight of the earth, of the velocity of electricity, and of light; chemical analyses of soils and plants; collection and publication of articles of science, accumulated in the offices of Government.

(4.) Institution of statistical inquiries with reference to physical, moral, and political subjects.

(5.) Historical researches, and accurate surveys of places celebrated in American history.

(6.) Ethnological researches, particularly with reference to the different races of men in North America; also explorations, and accurate surveys, of the mounds and other remains of the ancient people of our country.

I. TO DIFFUSE KNOWLEDGE.—*It is proposed to publish a series of reports, giving an account of the new discoveries in science, and of the changes made from year to year in all branches of knowledge not strictly professional.*

1. Some of these reports may be published annually, others at longer intervals, as the income of the Institution or the changes in the branches of knowledge may indicate.

2. The reports are to be prepared by collaborators, eminent in the different branches of knowledge.

3. Each collaborator to be furnished with the journals and publications, domestic and foreign, necessary to the compilation of his report; to be paid a certain sum for his labors, and to be named on the title-page of the report.

4. The reports to be published in separate parts, so that persons interested in a particular branch, can procure the parts relating to it, without purchasing the whole.

5. These reports may be presented to Congress, for partial distribution, the remaining copies to be given to literary and scientific institutions, and sold to individuals for a moderate price.

*The following are some of the subjects which may be embraced in the reports:—*

#### I. PHYSICAL CLASS.

1. Physics, including astronomy, natural philosophy, chemistry, and meteorology.
2. Natural history, including botany, zoology, geology, &c
3. Agriculture.
4. Application of science to arts.

#### II. MORAL AND POLITICAL CLASS.

5. Ethnology, including particular history, comparative philology, antiquities, &c.
6. Statistics and political economy.
7. Mental and moral philosophy.
8. A survey of the political events of the world; penal reform, &c.

#### III. LITERATURE AND THE FINE ARTS.

9. Modern literature.
10. The fine arts, and their application to the useful arts.
11. Bibliography.
12. Obituary notices of distinguished individuals.

II. TO DIFFUSE KNOWLEDGE.—*It is proposed to publish occasionally separate treatises on subjects of general interest.*

1. These treatises may occasionally consist of valuable memoirs translated from foreign languages, or of articles prepared under the direction of the Institution, or procured by offering premiums for the best exposition of a given subject.

2. The treatises to be submitted to a commission of competent judges, previous to their publication.

## DETAILS OF THE SECOND PART OF THE PLAN OF ORGANIZATION.

This part contemplates the formation of a Library, a Museum, and a Gallery of Art.

1. To carry out the plan before described, a library will be required, consisting, 1st, of a complete collection of the transactions and proceedings of all the learned societies of the world; 2d, of the more important current periodical publications, and other works necessary in preparing the periodical reports.

2. The Institution should make special collections, particularly of objects to verify its own publications. Also a collection of instruments of research in all branches of experimental science.

3. With reference to the collection of books, other than those mentioned above, catalogues of all the different libraries in the United States should be procured, in order that the valuable books first purchased may be such as are not to be found elsewhere in the United States.

4. Also catalogues of memoirs, and of books in foreign libraries, and other materials, should be collected, for rendering the Institution a centre of bibliographical knowledge, whence the student may be directed to any work which he may require.

5. It is believed that the collections in natural history will increase by donation, as rapidly as the income of the Institution can make provision for their reception; and, therefore, it will seldom be necessary to purchase any article of this kind.

6. Attempts should be made to procure for the gallery of art, casts of the most celebrated articles of ancient and modern sculpture.

7. The arts may be encouraged by providing a room, free of expense, for the exhibition of the objects of the Art-Union, and other similar societies.

8. A small appropriation should annually be made for models of antiquity, such as those of the remains of ancient temples, &c.

9. The Secretary and his assistants, during the session of Congress, will be required to illustrate new discoveries in science, and to exhibit new objects of art; distinguished individuals should also be invited to give lectures on subjects of general interest.

---

In accordance with the rules adopted in the programme of organization, each memoir in this volume has been favorably reported on by a Commission appointed

for its examination. It is however impossible, in most cases, to verify the statements of an author; and, therefore, neither the Commission nor the Institution can be responsible for more than the general character of a memoir.

---

The following rules have been adopted for the distribution of the quarto volumes of the Smithsonian Contributions:—

1. They are to be presented to all learned societies which publish Transactions, and give copies of these, in exchange, to the Institution.

2. Also, to all foreign libraries of the first class, provided they give in exchange their catalogues or other publications, or an equivalent from their duplicate volumes.

3. To all the colleges in actual operation in this country, provided they furnish, in return, meteorological observations, catalogues of their libraries and of their students, and all other publications issued by them relative to their organization and history.

4. To all States and Territories, provided there be given, in return, copies of all documents published under their authority.

5. To all incorporated public libraries in this country, not included in any of the foregoing classes, now containing more than 10,000 volumes; and to smaller libraries, where a whole State or large district would be otherwise unsupplied.

OFFICERS  
OF THE  
SMITHSONIAN INSTITUTION.

| SECTION I. Introductory statement . . . . .                                                                                                                                                                                                                                                                                                 | 1    |
| Correction of data . . . . .                                                                                                                                                                                                                                                                                                                | 3    |
| Table (A) of periodic times, distances, and masses of planets, respectively                                                                                                                                                                                                                                                                 | 3    |
| SECTION II. First approximation to a <i>Law</i> of planetary distances, with an approximate tabular arrangement of the system . . . . .                                                                                                                                                                                                     | 5    |
| Half-planet characteristics of the Earth and Venus . . . . .                                                                                                                                                                                                                                                                                | 6    |
| Half-planet characteristics of Uranus . . . . .                                                                                                                                                                                                                                                                                             | 7    |
| Ratios for half-planet terms; viz. :—                                                                                                                                                                                                                                                                                                       |      |
| $\frac{Neptune}{Uranus}$ , $\frac{Earth}{Mars}$ , and also $\frac{Mercury\ in\ aphelion}{Mercury\ in\ perihelion}$ ; which, with $r$ for the leading ratio of the system, all approximate to $r^3$ ; also ratio $\frac{Earth}{Venus}$ , approximating to $r^{\frac{1}{2}}$ . Symbolical arrangement representing planetary ratios . . . . . | 8    |
| Mode of computation of terms . . . . .                                                                                                                                                                                                                                                                                                      | 9    |
| LAWS OF PLANETARY DISTANCES, involving leading ratio $r$ , also $r^{\frac{3}{2}}$ , and $r^{\frac{1}{2}}$ .                                                                                                                                                                                                                                 |      |
| <i>2d Approximate Arrangement</i> of the system . . . . .                                                                                                                                                                                                                                                                                   | 10   |
| Question of regular variation of ratio $r$ considered . . . . .                                                                                                                                                                                                                                                                             | 11   |
| <i>Subsidiary Induction</i> in the region from <i>Saturn to Mars</i> inclusive . . . . .                                                                                                                                                                                                                                                    | 12   |
| Specific values of $r$ in the Planetary System . . . . .                                                                                                                                                                                                                                                                                    | 13   |
| <i>Completed Arrangement</i> of the <i>Planetary System</i> ; exhibiting the correspondence of <i>Law</i> with <i>Fact</i> , in Table (B) . . . . .                                                                                                                                                                                         | 14   |
| <i>System of Saturn</i> . . . . .                                                                                                                                                                                                                                                                                                           | 15   |
| Centre of gyration of a thin homogeneous ring is in the circumference of a circle bisecting the area of the ring . . . . .                                                                                                                                                                                                                  | 16   |
| A formula for the <i>centre of gyration</i> of any two equal masses similar to the reduced formula for the homogeneous ring . . . . .                                                                                                                                                                                                       | 17   |
| <i>Definite Arrangement</i> of the <i>Saturn System</i> in Table (C); the <i>rings</i> (referred to their centres of gyration) claiming their places as <i>satellites</i> . . . . .                                                                                                                                                         | 18   |
| Other relations in Saturn's System . . . . .                                                                                                                                                                                                                                                                                                | 19   |
| <i>Definite Arrangement</i> of <i>Jupiter's System</i> , in Table (D) . . . . .                                                                                                                                                                                                                                                             | 20   |
| <i>Approximate Arrangement</i> of the <i>System of Uranus</i> , in Table (E) . . . . .                                                                                                                                                                                                                                                      | 21   |

|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| <i>Summing up</i> of the preceding relations of distances in all the four systems                                                                               | 22     |
| Additional feature of resemblance of half-planets                                                                                                               | 23     |
| SECTION III. Description and illustration of the <i>Laplace Nebular Hypothesis</i>                                                                              | 24-29  |
| Formation of satellites and of Saturn's rings                                                                                                                   | 30, 31 |
| Small eccentricities                                                                                                                                            | 32     |
| Accounted for                                                                                                                                                   | 33     |
| <i>Existence of comets</i> explained                                                                                                                            | 34     |
| The Zodiacal Light, as discussed by Laplace                                                                                                                     | 35     |
| MODIFICATION OF LAPLACE'S NEBULAR HYPOTHESIS                                                                                                                    | 36-38  |
| Four specialities of the two <i>half-planets</i> Earth and Venus                                                                                                | 39     |
| Summation of the same                                                                                                                                           | 40     |
| <i>Determination of the mass of a (now) missing half-planet interior to Uranus</i>                                                                              | 41     |
| Disappearance of missing mass to be accounted for. It was <i>not</i> broken into asteroids                                                                      | 42     |
| <i>Ten coincidences</i> to show that the missing mass <i>was absorbed and combined with the forming Saturn</i>                                                  | 43     |
| An 11th coincidence shown in a <i>more Ancient Arrangement</i> of the material of the Solar System; the same being exhibited withal in Table (F)                | 43-45  |
| Values of the leading ratio $R_1$ in Table (F)                                                                                                                  | 45     |
| <i>Mass of the Asteroids</i>                                                                                                                                    | 46     |
| AGREEMENT of the <i>determination of the asteroid-mass</i> with that indicated by M. Le Verrier as obtained by a discussion of the <i>perturbations of Mars</i> | 47     |
| 1st <i>Approximation</i> to the <i>range</i> of the asteroids, by the use of the mass as previously determined                                                  | 49     |
| <i>Mercury's place</i> in Table (F). <i>Mercury includes mass of a whole and a half-planet. Eccentricity of his orbit</i> accounted for                         | 50     |
| <i>Mass and distance of a possible planet (or rather half-planet) interior to Mercury</i>                                                                       | 51     |
| <i>Such a mass, so situated, seems to be adequate to the perturbations in the orbit of Venus indicated by M. Le Verrier</i>                                     | 52     |
| Peculiar relations of the <i>living force of (simultaneous) rotation</i> of some of the planetary masses, and of Saturn's rings                                 | 53     |
| Application of other conditions appertaining to the ring-like form. Extension of formula                                                                        | 54     |
| Induction with respect to Saturn's rings                                                                                                                        | 55     |
| Application to Neptune and Uranus                                                                                                                               | 56     |
| <i>Consequent Arrangement</i> of planetary masses; the greater among the more remote, but the greatest not the most remote                                      | 57     |
| <i>Consequent and similar arrangement of masses in Saturn's System</i>                                                                                          | 58     |
| <i>Consequent and similar arrangement of Jupiter's System</i>                                                                                                   | 59     |
| <i>Arrangement of asteroid-mass. Same seems to be referable to two half-asteroid masses. Range of asteroids, and interference of Jupiter</i>                    | 60     |
| <i>Eccentricity of asteroid-orbits</i>                                                                                                                          | 61     |
| Approximate relations of the vis viva of (simultaneous) rotation of the <i>half-asteroid masses and that of Mars, respectively</i>                              | 63     |
| Reason for missing terms in planetary or satellite series of distances                                                                                          | 64, 65 |
| Vacuities in the Saturn-System                                                                                                                                  | 66     |
| Commensurability of periodic times. Influence of a <i>resisting medium</i> at the <i>formation</i> of the revolving bodies provided for by theory               | 67     |
| Special characteristics of the Moon and other satellites                                                                                                        | 68     |

| Explanation of the appearance of certain satellites of Jupiter as <i>dark spots</i> , in their <i>transit</i> across the face of their primary. Significance of the same as respects the <i>rotation, temperature, atmosphere, etc.</i> , of <i>satellites</i> . . . . .                                                                                                                                                                                                                  | 69     |
| Of the <i>Zodiacal Light</i> —M. Laplace's proof that the <i>Zodiacal Light</i> is not due to the sun's atmosphere . . . . .                                                                                                                                                                                                                                                                                                                                                              | 70     |
| His subsidiary hypothesis as to the constitution of the material which affords us the light . . . . .                                                                                                                                                                                                                                                                                                                                                                                     | 71     |
| <i>Eastern and Western</i> appearances of the light have occurred <i>simultaneously</i> . . . . .                                                                                                                                                                                                                                                                                                                                                                                         | 72     |
| Difficulty of supposing that the material is an <i>immediate solar appendage</i> . . . . .                                                                                                                                                                                                                                                                                                                                                                                                | 73     |
| The material a <i>terrestrial appendage</i> —its rarity . . . . .                                                                                                                                                                                                                                                                                                                                                                                                                         | 74     |
| The light, to a great extent, <i>transmitted light</i> . Observers at <i>diverse stations</i> see <i>different portions</i> of the material <i>illuminated</i> . . . . .                                                                                                                                                                                                                                                                                                                  | 75, 76 |
| Other phenomena attendant on the <i>transmission</i> of the light . . . . .                                                                                                                                                                                                                                                                                                                                                                                                               | 76, 77 |
| MODIFICATION of Rev. George Jones' <i>hypothesis of a nebulous terrestrial ring</i> . The material in form, a <i>girdle</i> . . . . .                                                                                                                                                                                                                                                                                                                                                     | 78     |
| How the <i>girdle</i> is maintained. Its time of revolution around the Earth <i>the same</i> with that of the Moon . . . . .                                                                                                                                                                                                                                                                                                                                                              | 79     |
| <i>Oval form</i> of the <i>girdle</i> , and certain conditions of <i>equilibrium</i> . . . . .                                                                                                                                                                                                                                                                                                                                                                                            | 80     |
| <i>Girdle, in equilibrio</i> , retains its <i>form</i> when the distance of the moon <i>varies</i> ; but its <i>dimensions change</i> . . . . .                                                                                                                                                                                                                                                                                                                                           | 81     |
| <i>Dimensions</i> of the <i>girdle</i> . . . . .                                                                                                                                                                                                                                                                                                                                                                                                                                          | 82     |
| Tidal action of the moon on the <i>girdle</i> . . . . .                                                                                                                                                                                                                                                                                                                                                                                                                                   | 83     |
| Other peculiarities are noticed in connexion with Consistency 60th, in . . . . .                                                                                                                                                                                                                                                                                                                                                                                                          | 100    |
| Curvature of parts of the <i>girdle</i> . . . . .                                                                                                                                                                                                                                                                                                                                                                                                                                         | 84     |
| <i>Five cases</i> of <i>variety of illumination</i> of the <i>girdle</i> , and therefore of <i>variety, etc.</i> , of the <i>Zodiacal Light</i> to be looked for . . . . .                                                                                                                                                                                                                                                                                                                | 85     |
| Variation of brightness probable . . . . .                                                                                                                                                                                                                                                                                                                                                                                                                                                | 86     |

| ARTICLE III. (No. 281.) ON THE GENERAL INTEGRALS OF PLANETARY MOTION. By SIMON NEWCOMB, Professor of Mathematics United States Navy. 1874. 4to. pp. 40.                                                                                                                                                                                                                                                                                                                                                |      |
| § 1. Introduction . . . . .                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 1    |
| § 2. Canonical Transformation of the Equations of Motion . . . . .                                                                                                                                                                                                                                                                                                                                                                                                                                     | 4    |
| § 3. Approximation to the Required Solutions by the Variations of the Arbitrary Constants in a First Approximate Solution . . . . .                                                                                                                                                                                                                                                                                                                                                                    | 9    |
| § 4. Formation of the Lagrangian Coefficients ( $a_i, a_k$ ), and Reduction of the Equations to a Canonical Form . . . . .                                                                                                                                                                                                                                                                                                                                                                             | 11   |
| § 5. Fundamental Relations between the Coefficients of the time, $b, \bar{b}_2$ , etc., considered as Functions of $c_1, c_2$ , etc. . . . .                                                                                                                                                                                                                                                                                                                                                           | 16   |
| § 6. Development of $\Omega, \Omega_2, \Omega'_2$ . . . . .                                                                                                                                                                                                                                                                                                                                                                                                                                            | 19   |
| § 7. Form of Second Approximation . . . . .                                                                                                                                                                                                                                                                                                                                                                                                                                                            | 24   |
| § 8. General Theorem . . . . .                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | 26   |
| § 9. Summary of Results . . . . .                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 28   |
| ARTICLE IV. (No. 267.) THE HAIDAH INDIANS OF QUEEN CHARLOTTE'S ISLANDS, BRITISH COLUMBIA; WITH A BRIEF DESCRIPTION OF THEIR CARVINGS, TATTOO DESIGNS, etc. By JAMES G. SWAN, Port Townsend, Washington Territory. 1874. 4to. pp. 22.                                                                                                                                                                                                                                                                   |      |
| ARTICLE V. (No. 277.) TABLES, DISTRIBUTION, AND VARIATIONS OF THE ATMOSPHERIC TEMPERATURE IN THE UNITED STATES, AND SOME ADJACENT PARTS OF AMERICA. Collected by the Smithsonian Institution, and discussed under the Direction of JOSEPH HENRY, Secretary. By CHARLES A. SCHOTT, Assistant U. S. Coast Survey; Member Nat. Acad. of Sci., Am. Phil. Socs. of Philadelphia and Washington, and of Academy of Sciences of Catania, Sicily. 1875. 4to. pp. 360. Nine Diagrams, Two Plates, Three Charts. |      |
| SECTION I. General remarks and explanation of tabular results . . . . .                                                                                                                                                                                                                                                                                                                                                                                                                                | vii  |
| Special table of corrections for daily variation of temperature in each month and the year, for every hour and for various combinations of hours . . . . .                                                                                                                                                                                                                                                                                                                                             | xiv  |
| Tables of mean temperature for each month, season, and the year at various stations, principally in North America . . . . .                                                                                                                                                                                                                                                                                                                                                                            | 1    |
| Graphical representation and explanation of the isothermal charts . . . . .                                                                                                                                                                                                                                                                                                                                                                                                                            | 101  |
| Deductions from the charts of the distribution of the mean annual temperature, and of the distribution of the temperature during the winter and the summer seasons . . . . .                                                                                                                                                                                                                                                                                                                           | 104  |

|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| SECTION II. Discussion of the daily fluctuation of the atmospheric temperature . . . . .                                                                                                               | 107  |
| Times of sunrise and sunset in different latitudes, and for every tenth day in each month . . . . .                                                                                                    | 113  |
| Tables of bi-hourly, hourly, and semi-hourly mean temperatures, for each month and the year at various places in North America . . . . .                                                               | 121  |
| Tables of differences from the mean of the day, of bi-hourly, hourly, and semi-hourly mean temperatures for each month and the year . . . . .                                                          | 137  |
| [For consolidated table of corrections for daily variation of temperature at four principal stations, in each month and the year, for every hour and for various combinations of hours, see page xiv.] |      |
| Systematic representation of the daily fluctuation of the temperature, by means of a periodic function . . . . .                                                                                       | 153  |
| Analysis of the daily fluctuation . . . . .                                                                                                                                                            | 154  |
| Variability of the temperature at any hour of the day from the normal value of that hour . . . . .                                                                                                     | 162  |
| SECTION III. The annual fluctuation of the temperature expressed in terms of a periodic function . . . . .                                                                                             | 169  |
| Table of computed annual fluctuation of the temperature at 46 stations . . . . .                                                                                                                       | 175  |
| Discussion of the results for dates of mean annual values, and for maxima and minima; and annual range in connection with the geographical distribution of the stations . . . . .                      | 180  |
| Examination into alleged interruption in the regularity of the annual fluctuation at certain epochs, with tables of temperature of each day of the year, deduced from a series of years . . . . .      | 183  |
| Investigation of the variability of the temperature of any one day in a series of years . . . . .                                                                                                      | 197  |
| Inequality in the epoch of the minima and maxima of the annual fluctuation                                                                                                                             | 199  |
| Tables of observed extremes of temperatures, arranged by months, for a selected number of stations . . . . .                                                                                           | 202  |
| Analysis of tabular results for greatest heat and greatest cold with regard to geographical distribution . . . . .                                                                                     | 226  |
| Extreme annual range of temperature and monthly absolute variability, exhibition of the law of annual distribution . . . . .                                                                           | 227  |
| Tables of the mean annual temperature, principally in the United States, for a succession of years, from the earliest records to the close of the year 1870 . . . . .                                  | 228  |
| Investigation of the secular variation of the annual mean temperature, and of the permanency of the climate . . . . .                                                                                  | 302  |
| Comparison of the secular variation of the temperature with the variations in the frequency of the solar-spots . . . . .                                                                               | 314  |
| Comparison of the secular variation in the temperature and rain-fall in the United States . . . . .                                                                                                    | 315  |
| Comparison of the secular variation in the temperature with the average annual direction of the wind . . . . .                                                                                         | 316  |
| Range of variability in the secular variation of the annual temperature . . . . .                                                                                                                      | 318  |
| Secular variation in the annual minima and maxima, compared with the variation in the annual means . . . . .                                                                                           | 319  |
| LIST OF STATIONS . . . . .                                                                                                                                                                             | 321  |
| LIST OF OBSERVERS . . . . .                                                                                                                                                                            | 333  |
| INDEX . . . . .                                                                                                                                                                                        | 341  |

STATEMENT AND EXPOSITION

OF

CERTAIN HARMONIES

OF

THE SOLAR SYSTEM.

BY

STEPHEN ALEXANDER, LL.D.,

PROFESSOR OF ASTRONOMY IN THE COLLEGE OF NEW JERSEY.

[ACCEPTED FOR PUBLICATION, JULY, 1874.]

WASHINGTON,

MARCH, 1875.

PHILADELPHIA:  
COLLINS, PRINTER, 705 JAYNE STREET.

## ADVERTISEMENT.

---

THE principal part of the following Memoir on Certain Harmonies of the Solar System was read before the American National Academy of Sciences, at its meeting in April, 1873, and some additional portions of the same, at the meeting in April, 1874.

In accordance with usage in such cases the whole is now presented to the public through the Smithsonian Contributions to Knowledge.

JOSEPH HENRY,

*Secretary S. I.*

*Note by the Author.*—After reading the whole memoir, a synopsis of the principal relations may be obtained by a reperusal and comparison of the Tables (B) to (F) inclusive, with their explanations; and, especially, the Summation of Consistencies at the end.

# CONTENTS.

*N.B.* The references are to the articles, not to the pages.

## SECTION I.

Introductory statement, 1.

Correction of data, 3.

Table (A) of periodic times, distances, and masses of planets, respectively, 3.

## SECTION II.

First approximation to a *Law* of planetary distances, with an approximate tabular arrangement of the system, 5.

Half-planet characteristics of the Earth and Venus, 6.

Half-planet characteristics of Uranus, 7.

Ratios for half-planet terms; viz:—

$\frac{\text{Neptune}}{\text{Uranus}}$ ,  $\frac{\text{Mars}}{\text{Earth}}$ , and also  $\frac{\text{Mercury in aphelion}}{\text{Mercury in perihelion}}$ ; which, with  $r$  for the leading ratio of the system, all approximate to  $r^2$ ; also ratio  $\frac{\text{Earth}}{\text{Venus}}$ , approximating to  $r^{\frac{1}{2}}$ . Symbolical arrange-

ment representing planetary ratios, 8.

Mode of computation of terms, 9.

LAWs of PLANETARY DISTANCES, involving leading ratio  $r$ , also  $r^{\frac{1}{2}}$ , and  $r^{\frac{1}{3}}$ . *2d Approximate Arrangement* of the system, 10.

Question of regular variation of ratio  $r$  considered, 11.

*Subsidiary Induction* in the region from *Saturn* to *Mars* inclusive, 12.

Specific values of  $r$  in the Planetary System, 13.

*Completed Arrangement* of the *Planetary System*; exhibiting the correspondence of *Law* with *Fact*, in Table (B), 14.

*System of Saturn*, 15.

Centre of gyration of a thin homogeneous ring is in the circumference of a circle bisecting the area of the ring, 16.

A formula for the *centre of gyration* of any two equal masses similar to the reduced formula for the homogeneous ring, 17.

*Definite Arrangement* of the *Saturn System* in Table (C); the *rings* (referred to their centres of gyration) claiming their places as *satellites*, 18.

Other relations in *Saturn's System*, 19.

*Definite Arrangement* of *Jupiter's System*, in Table (D), 20.

*Approximate Arrangement* of the *System of Uranus*, in Table (E), 21.

*Summing up* of the preceding relations of distances in all the four systems, 22.

Additional feature of resemblance of half-planets, 23.

## SECTION III.

- Description and illustration of the *Laplace Nebular Hypothesis*, 24 to 29 inclusive.  
 Formation of satellites and of Saturn's rings, 30 and 31.  
 Small eccentricities, 32. Accounted for, 33.  
*Existence of comets* explained, 34.  
 The Zodiacal Light, as discussed by Laplace, 35.  
 MODIFICATION OF LAPLACE'S NEBULAR HYPOTHESIS, 36 to 38.  
 Four specialities of the two *half-planets* Earth and Venus, 39.  
 Summation of the same, 40.  
*Determination of the mass of a (now) missing half-planet interior to Uranus*, 41.  
 Disappearance of missing mass to be accounted for. It was *not* broken into asteroids, 42.  
*Ten coincidences* to show that the missing mass *was absorbed and combined with the forming Saturn*, 43.  
 An 11th *coincidence* shown in a *more Ancient Arrangement* of the material of the Solar System; the same being exhibited withal in Table (F), 43, 44, and 45.  
 Values of the leading ratio *R*, in Table (F), 45.  
*Mass of the Asteroids*, 46.  
 AGREEMENT of the *determination* of the *asteroid-mass* with that indicated by M Le Verrier as obtained by a discussion of the *perturbations of Mars*, 47.  
 1st *Approximation* to the *range* of the asteroids, by the use of the mass as previously determined, 49.  
*Mercury's place* in Table (F). Mercury includes mass of a *whole and a half-planet*. *Eccentricity of his orbit* accounted for, 50.  
*Mass and distance* of a possible *planet* (or rather half-planet) *interior to Mercury*, 51.  
 Such a mass, so *situated*, seems to be adequate to the *perturbations* in the orbit of Venus indicated by M. Le Verrier, 52  
 Peculiar relations of the *living force* of (*simultaneous*) *rotation* of some of the planetary masses, and of Saturn's rings, 53.  
 Application of other conditions appertaining to the ring-like form. Extension of formula, 54.  
 Induction with respect to Saturn's rings, 55.  
 Application to Neptune and Uranus, 56.  
*Consequent Arrangement* of planetary masses; the greater among the more remote, but the greatest not the most remote, 57.  
*Consequent and similar* arrangement of masses in *Saturn's System*, 58.  
*Consequent and similar* arrangement of *Jupiter's System*, 59.  
*Arrangement of asteroid-mass*. Same seems to be referable to *two half-asteroid masses*. *Range of asteroids*, and interference of *Jupiter*, 60.  
*Eccentricity of asteroid-orbits*, 61.  
 Approximate relations of the vis viva of (*simultaneous*) *rotation* of the *half-asteroid masses* and *that of Mars*, respectively, 63.  
 Reason for missing terms in planetary or satellite series of distances, 64 and 65.  
 Vacuities in the Saturn-System, 66.  
 Commensurability of periodic-times. Influence of a *resisting medium* at the *formation* of the revolving bodies provided for by theory, 67.  
 Special characteristics of the Moon and other satellites, 68.  
 Explanation of the appearance of certain satellites of Jupiter as *dark spots*, in their *transit* across the face of their primary. Significance of the same as respects the *rotation, temperature, atmosphere, etc.*, of *satellites*, 69.  
 Of the *Zodiacal Light*—M. Laplace's proof that the Zodiacal Light is not due to the sun's atmosphere, 70.  
 His subsidiary hypothesis as in the constitution of the material which affords us the light, 71.  
*Eastern and Western* appearances of the light have occurred *simultaneously*, 72.  
 Difficulty of supposing that the material is an *immediate solar appendage*, 73.

- The material a *terrestrial appendage*—its rarity, 74.
- The light, to a great extent, *transmitted light*. Observers at *diverse stations* see *different portions* of the material *illuminated*, 75 and 76.
- Other phenomena attendant on the *transmission* of the light, 76 and 77.
- MODIFICATION of Rev. George Jones' *hypothesis of a nebulous terrestrial ring*. The material in form, a *girdle*, 78.
- How the *girdle* is maintained. Its time of revolution around the Earth *the same with that of the Moon*, 79.
- Oval form of the girdle*, and certain conditions of *equilibrium*, 80.
- Girdle, in equilibrio*, retains its *form* when the distance of the moon *varies*; but its *dimensions change*, 81.
- Dimensions of the girdle*, 82.
- Tidal action of the moon on the *girdle*, 83.
- Other peculiarities are noticed in connexion with Consistency 60th, in 100.
- Curvature of parts of the *girdle*, 84.
- Five cases of variety of illumination* of the *girdle*, and therefore of variety, etc., of the *Zodiacal Light* to be looked for, 85.
- Variation of brightness probable, 86.
- Observations of phenomena, presented by the *Zodiacal Light*, and statements of the Moon's position at the times of observation, 87.
- "Moon" *Zodiacal Light*, 88.
- Various additional observations, including those of the "pulsations" of the *Zodiacal Light*, 89 to 93.
- Absence of *parallax* of the *Zodiacal Light* accounted for, 94.
- Summary of what seem to be eight *special coincidences of phenomena* with the requirements of the *theory*, 95.
- Origin of the Girdle*, 96.
- Conjecture as to the *Aurora Borealis*, 97.
- Analogies and differences of the *Girdle* and *Saturn's Dusky Ring*, 98.
- Close correspondence* in the position of the *planes of the planetary orbits in ancient times*. Conjecture as to the reason why the *Sun's equator* makes an angle with those planes, the mean value of which is nearly  $5^\circ$ . Also as to the *derivation* of the *great planetary masses* from *different half-spheroids of the Sun*; and which from which. Harmonious relations developed by John N. Stockwell, M.A., 99.
- Greater inclination of the orbits of outer satellites to the planes of the equators of their respective primaries, and especially the great inclination of the Moon's orbit to the plane of the equator of the Earth; and the yet greater inclination of the orbits of the satellites of Uranus to the plane of the equator of their primary. *Reasons assigned* for these peculiarities, 100.
- The Minor System*, 101.
- Saturn and the Earth (the Saturn of the Minor System) compared, 102.
- Relations of great planetary masses, in the *Ancient State* of the Solar System. Possible order and character of successive development, 104.
- Illustrations of *Kirkwood's Analogy*, 106.
- Failure of the formula derived from *Kirkwood's Analogy* in the case of *Uranus*. Reason for this, 107.
- Approximate coincidence of the result of the same formula with fact, in the case of Mars; admitting the subsidiary hypothesis of *half asteroid masses*, 108.
- The (so-called) "*Bode's Law*," 109.
- Immediately after these we have the *Summation of Coincidences*, 62 in number, 110.
- Lastly, we have *Supplementary Notes* (A) and (B).

## CERTAIN HARMONIES OF THE SOLAR SYSTEM.

### SECTION I.

#### INTRODUCTORY.

(1) KEPLER'S 3d Law is ordinarily expressed by saying that the squares of the periodic times of the several planets of the solar system are to one another, respectively, as the cubes of their distances from the sun. The same law includes also the periodic comets, and it is, in like manner, applicable to the satellite systems.

But from this we do not learn that any laws are to be found determining the ratios of the distances themselves.

It will be one main object of the present discussion to show that such laws exist, and precisely what they are—generality and precision being characteristics of every law of nature.<sup>1</sup>

(2) Approximations to the laws in question have, from time to time, been exhibited, by the author of this paper, to the American Association for the Advancement of Science, at several of their meetings, beginning with that at New Haven, in 1850, and more especially, also, that at Montreal, in 1857; Baltimore, in 1858; and Springfield, Massachusetts, in 1859; but it is only within the past few months, or even almost up to this present time (July, 1874), that the entire form and consistency of the results hereinafter exhibited have been quite fully made out.

(3) All that is to be stated will, it is conceived, be the more readily intelligible by proceeding, as occasion may seem to require, *inductively*, and consequently following, to some extent, the order of discovery.

Antecedently even to this, however, it seemed to be desirable to discuss anew the expressed values of the distances in question, and this, in view of the fact, that Kepler's 3d Law is itself slightly modified by the consideration due to the *masses* of the revolving bodies.

Thus if  $M$  represent the mass of the sun, and  $m, m'$  the respective masses of any two planets, while  $a, a'$  represent their mean distances from the sun, and  $T, T'$  represent their periodic times, we have

$$\left. \begin{aligned} \left(\frac{T'}{T}\right)^2 &= \left(\frac{a'}{a}\right)^3 \times \frac{M+m}{M+m'}, \text{ or} \\ \left(\frac{T'}{T}\right)^2 \times \frac{M+m'}{M+m} &= \left(\frac{a'}{a}\right)^3 \end{aligned} \right\} \dots (1);$$

---

<sup>1</sup> The so-called Law of Bode or of Titius, it need scarcely be said, fails in both these respects.

When  $m$  and  $m'$  are mere particles of matter *Eqs. (1)* are both reduced to

$$\left(\frac{T'}{T}\right)^2 = \left(\frac{a'}{a}\right)^3 \dots (1).$$

It may be convenient to regard, once for all,  $a$ ,  $m$ , and  $T$ , in so far as they appear, as being special for the earth, while  $a'$ ,  $m'$ , and  $T'$  respectively represent like quantities in the instance of any other planet.

Now  $T'$  and  $T$  having both been well ascertained, and being themselves constant, the same is true of their ratio, which involves also the *constant value* of  $\left(\frac{T'}{T}\right)^2$ ; and hence it follows that, to preserve *Eq. (1)*, we must have the value of  $\left(\frac{a'}{a}\right)^3$  also *constant*, and this, although the accepted value of  $a$ , the earth's mean distance from the sun, which is the unit of measurement, may itself require correction in comparison with other standards. If  $a$  then be diminished, every other mean distance  $a'$ , as it is represented in *Eq. (1)'*, will be found to be diminished in the same ratio; and thus, while the numbers representing them remain *unchanged*, "all the distances have to be reckoned on a new scale."<sup>1</sup>

Next, as respects the modifying factor  $\frac{M+m'}{M+m}$ , in the second of *Eqs. (1)*. As it is moreover true, that  $M$  itself varies directly as  $a^3$ ; if  $a^3$  be *diminished*,  $M$  will be *diminished* in the same ratio, and *the like* will be true of  $m'$  represented, as usual, in terms of  $M$  as the measuring unit; so that all such masses will be represented by the same numbers as before, but all, as in the case of the distances, "reckoned on a new scale," while *the mass of the earth* will, in this comparison, be *increased*, as that will vary *inversely* as  $a^3$ .

Now the more recent determination of the solar parallax requiring that the actual value of  $a$  should be diminished, it became requisite for the accurate determination of the values of the mean distances of such other planets as have ascertained and appreciable masses, that those values, as already intimated, should be rediscussed.

This has been done with the aid of logarithms computed to ten decimal places of figures; and the results, to the seventh decimal place inclusive, are exhibited in Table (A), in which withal, in their appropriate column, are also the values of the masses made use of, with indications of the authorities to which they are referable.

The densities which besides are exhibited in Table (A), will be found to vary more or less from those hitherto ordinarily accepted. This is due to the increase in the relative mass of the earth, and also to the more accurate determination of the masses of the planets.

The arrangement of the series of planets begins with the most distant, as that will be found to be the more convenient for the application of these data to the special purposes of the whole investigation.

---

<sup>1</sup> Sir J. Herschel's *Outlines of Astronomy*, 11th edition (357 c.)

The results given are those which are respectively consistent with two values of the solar parallax; viz., Prof. Newcomb's value  $\pi = 8''.848$ ,<sup>1</sup> and that which some prefer,  $\pi = 8''.78$ .

REMARKS.—The authorities for the *Periodic Times* are :—

*Uranus.* From Prof. NEWCOMB'S Tables of Uranus.

*Earth.* The sidereal year of HANSEN and OLUFSEN, as quoted by Prof. WATSON. *Theor. Astronomy*, Table XXI.

The other periodic times are those usually accepted.

For the *Masses* we have—

*Neptune.* The Pulkova deduction, furnished by Prof. NEWCOMB.

*Uranus.* From Prof. NEWCOMB'S Tables of Uranus.

*Saturn.* BESSEL, *Comptes Rendus*, 1841.

*Jupiter.* BESSEL, *Die Masse des Jupiter*, p. 64. [Its great accuracy is confirmed by Prof MÖLLER'S deduction from the perturbations of *Faye's Comet*, and by the recent investigations by Dr. KRUEGER, of the perturbations of *Themis*, *Ast. Nachrichten*, No. 1941.]

*Mars.* HANSEN and OLUFSEN'S mass, as quoted by Prof. HILL. *Tables of Venus*, p. 2.

*Earth.* Prof. NEWCOMB'S *Investigation of the Distance of the Sun*, etc., § 11 (with  $\pi = 8''.848$ ).

With  $\pi = 8''.78$ , the mass was deduced, with a change of value proportioned to  $\pi^2$ .

*Venus.* Prof. HILL, *Tables of Venus*, p. 2.

*Mercury.* ENCKE, *Astronomische Nachrichten*, No. 443.

The columns of densities have been computed by the aid of the other data. If we admit for *Venus* the mass  $\frac{1}{437246}$ , to which some indications point (*Hill's Tables*, p. 2), then the density of that planet with the value of the solar parallax =  $8''.848$ , will be represented by 0.773, or for the value of  $\pi = 8''.78$ , the representative density will be 0.791 +. The only change in the value of the mean distance of Venus will then be that the last decimal figure (with  $\pi = 8''.848$ ) will read 1 + instead of 2 —.

<sup>1</sup> Smithsonian Contributions to Knowledge—Investigation of the Distance of the Sun, etc., § 10.

## SECTION II.

ON THE LAWS OF ARRANGEMENT OF THE DISTANCES, BOTH OF PLANETS AND THEIR SATELLITES, FROM THEIR RESPECTIVE CENTRES OF ATTRACTION.

(4) The object of this section is to indicate distinctly the ratios which prevail among the planetary and satellite distances from their respective centres, and also the *laws* which include the same; *without the introduction in this same connexion of any physical hypothesis on which those laws seem to be founded, or of which they are the exponents.*

The hypothesis which seems to reconcile and explain those laws, *as well as a number of other phenomena*, will be considered in a subsequent section.

(5) The first correspondence and arrangement of ratios that will be noticed, may be thus stated: Beginning with the mean distance of Neptune as found in Table (A) in (3), if of this we take  $\frac{5}{9}$ , and of that fractional product, again,  $\frac{5}{9}$ , etc., etc.; then, among the terms in the geometrical progression thus developed, in addition to that pertaining to Neptune, we shall find those which respectively, in their order, exhibit close approximations to the mean distances of the two great planets Saturn and Jupiter; another having an appropriate position among the asteroids;<sup>1</sup> with, again, others which respectively exhibit close approximations to the mean distance of Mars, and that of Mercury *in aphelion*; all which can be distinctly traced in the following tabular arrangement, in which the approximations are carried to the third place of decimals inclusive; though the computations were extended to the fifth place. In the third column, it will be remembered, every term after the first, is  $\frac{5}{9}$  of that immediately preceding; so that the ratio of every one to its next succeeding term will be that of 9 to 5 = to  $\frac{9}{5} = \frac{1.8}{1} = 1.8$ ; a statement which, in certain comparisons, will be found to be more convenient than the other.

In this arrangement the column under the title of *Law* exhibits the results in accordance with the (approximate) law of succession of the terms as now explained; in comparison, respectively, with the recorded distances found in the column of *Fact*; the terms in the column of *Law* forming a series in geometrical progression, the ratio being 1.8.

## 1st Approximate Arrangement.

<sup>1</sup> Of which more hereafter.

(6) An inspection of what is here exhibited will at once reveal the fact that the Earth and Venus seem to have characteristics of *half-planets*; the *one* term, 0.884 (in the series), pertaining to them, being indicative of a distance between those of the two planets at which their masses should be united; and which is designated as *limit* ( $\oplus \varphi$ ).

[To avoid circumlocution, such an arrangement as this, will be termed a *half-planetary arrangement*, and the planets subject to it, be, at times, designated as *half-planets*; those situated, as Uranus and the Earth are, *without* the intervening *limit*, being styled *exterior half-planets*; while those, like Venus, *within the limit*, are specially designated as being *interior half-planets*; Uranus being regarded as an *exterior half-planet* as well as the Earth. For the ratio of the mean distance of Neptune to that of Uranus is very *nearly the same as that of Mars to the Earth's*; viz., a very little greater than the ratio of  $1\frac{1}{2}$  to 1. And so<sup>1</sup> the *limit* ( $\upsilon$ ) in the *progression* is very nearly the *same fraction* of the term for *Uranus* in the column of Fact, that the *limit* ( $\oplus \varphi$ ) is of the *Earth's distance*; viz. very nearly  $\frac{9}{10}$ , in both cases.]

(7) Uranus, then, like the earth, has the characteristics of an *exterior half-planet*;<sup>2</sup> though there is no other half-planet (analogous to Venus) apparent between *limit* ( $\upsilon$ ) and Saturn. But *the region* of the system where the appropriate term for *such* a half-planet should be found has been marked in the tabular arrangement, and its symbol ( $\textcircled{\text{v}}$ ) shows that *it* would belong to a *half-planet interior* to Uranus; such as Venus is in the region interior to the Earth's place.

(8) Now the ratios for the mean distances from the Sun of the *exterior half-planet terms*, are as follows:—

$$\left. \begin{aligned} \frac{\text{Neptune}}{\text{Uranus}} &= 1.56681 \\ \frac{\text{Mars}}{\text{Earth}} &= 1.52369 \\ \frac{\text{Mercury in aphelion}}{\text{Mercury in perihelion}} &= 1.51768 \end{aligned} \right\} \text{Mean} = 1.53606;$$

while it is also true, with respect to the ratio for other than half-planet distances [which =  $\frac{9}{5}$  or  $\frac{1.8}{1}$  very nearly], that

$$(1.8)^{\frac{2}{3}} = 1.55401,$$

agreeing very nearly with the preceding; so that, *r* being the ratio for other than half-planets, the ratio for the *exterior half-planets* is  $r^{\frac{2}{3}}$ .

Also, as again respects mean distances from the Sun,

$$\frac{\text{Earth}}{\text{Venus}} = 1.38249.$$

<sup>1</sup> Having all the while in view the table of the first Approximate Arrangement under discussion.

<sup>2</sup> This was not discerned until just before the Meeting of the American Association for the Advancement of Science, in Baltimore, in 1858. It is just the non-perception of a *half-planet* relationship, that has seriously troubled most of the investigations into the arrangements, etc., of the planetary system, whether purely speculative or otherwise.

But  $r$  being still = 1.8, the square root of  $r$ , or

$$r^{\frac{1}{2}} = 1.34161,$$

so that,  $r$  being still the leading ratio, the ratio for the interior half-planet Venus, is  $r^{\frac{1}{2}}$ ; and this planet furnishes the only existing example of its kind in the planetary system. Another will appear in the system of Saturn.

The relations thus ascertained may be symbolized as follows; the dependence of a following term on that from which it is derived being indicated by a brace connecting the two, and the power of  $r$  involved marked outside of the brace: as, for example, we have

$$\begin{array}{r}
 \text{Mars} \\
 \text{Earth} \\
 \dots \dots r^{\frac{1}{2}} \\
 \text{Venus}
 \end{array}
 \left\{ \begin{array}{l}
 \text{Planet} \\
 \left\{ \frac{1}{2} \text{ planet} \right\} \\
 \dots \dots \text{Pl. limit} \\
 \left\{ \frac{1}{2} \text{ planet} \right\}
 \end{array} \right\} r^{\frac{1}{2}}
 \left\{ \dots \dots \left\{ \begin{array}{l}
 \text{Earth} \\
 \text{Venus}
 \end{array} \right\} \text{Limit } (\oplus \varphi) \right\} r$$

Planetary limit. . . . . Ap helion of Mercury.

(9) This being kept in view, it will be apparent from what precedes, that the rules now established for the derivation of all the distances in the planetary arrangement subsequent to the first, are as follows:—

[Leading ratio  $r$  being = 1.8 very nearly]

Rule 1st.—When the term in question in the series of planetary distances is other than that pertaining to a half-planet, the value of that term may be obtained by dividing the value of the term immediately preceding by the leading ratio.

Examples.—Thus, as indicated by the symbols,

$$\begin{aligned}
 \frac{\text{Saturn term}}{r} &= \text{Mean distance of Jupiter} \\
 \frac{\text{Mars term}}{r} &= \text{Limit } (\oplus \varphi); \text{ and} \\
 \frac{(\oplus \varphi)}{r} &= \text{Ap helion distance of Mercury.}
 \end{aligned}$$

[This (incidentally it may be) includes the term for Mercury,<sup>1</sup> with the variety, that the term which immediately precedes (and which is to be employed in that computation) is the term pertaining to the half-planet Venus; though Mercury itself is not a half-planet, but even has characteristics approaching to those of a double-planet.]

Rule 2d.—The value of any term in the series of exterior half-planets may be obtained by dividing the value of the term immediately preceding that in the planetary arrangements, by  $r^{\frac{3}{2}}$ .

[The Examples are: The respective mean distances of Uranus and the Earth, and the perihelion distance of Mercury. Thus,

$$\frac{\text{Mars term}}{r^{\frac{3}{2}}} = \text{Earth term.}$$

---

<sup>1</sup> Incidentally, it may be; for Mercury's mean distance has other relations; as will appear in Section III.

*Rule 3d.*—The value of *any term* in the series of *interior* half-planets may be obtained by dividing the value of the term of the planetary arrangement immediately preceding *that*, by  $r^{\frac{1}{2}}$ .

[*Examples* are: The mean distance of Venus, and that due to the *missing interior half-planet*, next in the arrangement to the *exterior* half-planet Uranus. Thus

$$\frac{\text{Earth term}}{r^{\frac{1}{2}}} = \text{Venus term.}]$$

With  $D'$ , or  $D''$ , or  $D'''$ , as the case may be, for the value of the distance in question, and  $D$  that to which that value is referred, we have

For *Case* under *Rule First*,

$$D' = \frac{D}{r}; \text{ whence, withal, } r = \frac{D}{D'} \dots \dots (a)$$

$$\left[ \text{For Mercury, } D' = \frac{(d)}{r} \right]^1$$

For *Case* under *Rule Second*,

$$D'' = \frac{D}{r^{\frac{3}{2}}}$$

For *Case* under *Rule Third*,

$$D''' = \frac{D}{r^{\frac{5}{2}}}$$

From these equations we also learn, that

$$\left. \begin{aligned} \frac{D'}{D}, \text{ or } \frac{D'}{(d)}, \text{ each} &= \frac{1}{r}, \\ \frac{D''}{D} &= \frac{1}{r^{\frac{3}{2}}}, \text{ and} \\ \frac{D'''}{D} &= \frac{1}{r^{\frac{5}{2}}} \end{aligned} \right\} \dots \dots (P)$$

(10) These equations express the laws of apportionment of the planetary distances; which are these:—

*Laws of Apportionment of the Planetary Distances.*

[Value of  $r = 1.8$ , very nearly.]

**LAW FIRST.** For any term subsequent to the first, in the series of terms of planetary distances; and *other than* a half-planetary term:—

$$\text{succeding term} \quad : \quad \text{prec. term} \quad : : \quad 1 \quad : \quad \text{leading ratio } r.$$

**LAW SECOND.** For an *exterior* half-planetary term:—

$$\text{ext. half-planet. term} \quad : \quad \text{prec. term} \quad : : \quad 1 \quad : \quad \sqrt[3]{\text{power of leading ratio } r, \text{ i. e. } r^{\frac{3}{2}}}.$$

**LAW THIRD.** For an *interior* half-planetary term.

$$\text{int. half-planet. term} \quad : \quad \text{prec. term} \quad : : \quad 1 \quad : \quad \text{square root of leading ratio } r, \text{ or } r^{\frac{1}{2}}.$$

---

<sup>1</sup> ( $d$ ) being the term pertaining to the *interior half-planet Venus*.

In the second approximate arrangement which follows, the dependence of the value of one term on that of another is indicated by *the brace* connecting them, and the power of  $r$  in question is also shown; the half-planetary terms have their names printed in italics; while Mercury's name (in view of the peculiarity of that planet) appears in capitals: other symbols, etc., as heretofore.

The leading ratio here accepted, after many trials of *it* and of other ratios, is 1.805.

*Second Approximate Arrangement of the Planetary System. [Value of Leading Ratio 1.805].*

(11) The approximation of law to fact here shown, though in the main very close, yet exhibits some terms in which the discrepancy is a greater fraction of the whole than seems to be quite tolerable, in view of the accuracy of the other terms.

Then, too, the last column of the arrangement here shows a tendency in the difference of law from fact to be *negative* for the *first* part of the series of terms, *but positive afterwards*; as though the value of the leading ratio were in excess for the one portion, and thus had given the results in general too small; but the same value of the ratio having been too small in the case of the remaining terms, had consequently given results too large. All this makes it not improbable that the leading factor  $r$ , from first to last, should regularly increase, beginning *below* the mean value of 1.805, and ending *above* the same; the increase, however, in any event, being *very small*.

To ascertain whether this is so, it will be found advisable to institute a separate induction within the narrower limits of the region from Saturn to Mars inclusive,

in which we possess three out of the four requisite terms;<sup>1</sup> the fourth (the asteroid term or limit (A)) to be accurately determined by the process here proposed, and its value *thus* obtained to be made *the criterion* for the comparison of its value as ascertained in the more extended series. In the several instances of the three planets here in question, there are withal no *half-planet* relations, and the fourth term being a *limit* in the regular series in which *r* enters, the half-planet relation does not pertain to it; so that the character of the leading factor *r*, as to variability or otherwise, is here to be sought for.

(12) Now the *existing* mean distances from the sun in this region, together with the *asteroid limit* (A), may be arranged as follows, viz. :—

|                     | Dist. from Sun. <sup>2</sup> | Log. of Ratios. | Difference. |
|---------------------|------------------------------|-----------------|-------------|
| Saturn . . . . .    | 9.53885 +                    | 0.2632591 —     |             |
| Jupiter . . . . .   | 5.20280                      | 0.2655331 —     | + 0.002274  |
| Limit (A) . . . . . | (2.82296 —)                  | 0.2678071 —     | 0.002274    |
| Mars . . . . .      | 1.52369 +                    |                 |             |

The log. differences being equal, the ratios themselves increase *in geometrical progression*.

But if the arrangement be made with the ratios increasing *in arithmetical progression*, we shall have—

|                     | Dist. from Sun. <sup>2</sup> | Ratios. | Difference. |
|---------------------|------------------------------|---------|-------------|
| Saturn . . . . .    | 9.53885 +                    | 1.83341 |             |
| Jupiter . . . . .   | 5.20280                      | 1.84305 | + 0.00964   |
| Limit (A) . . . . . | (2.82293 —)                  | 1.85269 | 0.00964     |
| Mars . . . . .      | 1.52369 +                    |         |             |

Now we do not know enough of the nature of the case to decide which of these conditions ought to prevail, though the analogy of logarithms etc. would lead us to suppose that the ratios themselves should increase in arithmetical progression. But, happily, such a decision is of no moment practically; since the differences in question are so small, that the value of the limit (A) in the one case differs from that in the other only in the fifth decimal place.

So the value of the limit (A) = 2.82293—, which is that due to the increase of the ratio in *arithmetical progression*, will be accepted, and the same will be adopted; and then, as heretofore intimated, this value will be made the *criterion* for the comparison of the value as ascertained in the more extended series. This standard value, being withal a direct derivation from fact, in its own special region, will hereafter be inserted as a *limit* in the column of *Fact*, the figures being inclosed in a parenthesis.<sup>3</sup>

<sup>1</sup> In the order of discovery, it was in *this region* that the approximation of the series of distances to a geometrical progression, with the ratio = 1.8 nearly, was first discerned.

<sup>2</sup> See Table (A), in (3).

<sup>3</sup> This value, 2.82293, is greater than the mean of the distances from the sun of 122 known asteroids, which is only 2.70282. But then about  $\frac{7}{12}$  of that number are distances below the mean; leaving but  $\frac{5}{12}$  above the same. So that it seems not unreasonable to suppose that were many more included, which mostly are now unknown—partly, it may be, because of their greater distance—the mean

(13) The *increment* of the leading ratio, or factor  $r$ , having been ascertained to be *real* for the region thus examined, an application of the rule which that implies was tried throughout the planetary system; and after an enormous number of such tentative processes, the following local values of  $r$  were found to give the most consistent results, the values of  $r$ , it will be seen, increasing withal in arithmetical progression.

*Values of  $r$  in the Planetary System.*

| <i>Region.</i>                                                        | <i>Factor <math>r</math>.</i> |                                                                    |
|-----------------------------------------------------------------------|-------------------------------|--------------------------------------------------------------------|
| Neptune to <i>limit</i> (U) . . . . .                                 | 1.7770                        | 0.0138<br>0.0138<br>0.0138<br>0.0138<br>0.0138<br>0.0138<br>0.0138 |
| <i>Limit</i> (U) to Saturn . . . . .                                  | 1.7908                        |                                                                    |
| Saturn to Jupiter . . . . .                                           | 1.8046                        |                                                                    |
| Jupiter to <i>limit</i> (A) . . . . .                                 | 1.8184                        |                                                                    |
| <i>Limit</i> (A) to Mars . . . . .                                    | 1.8322                        |                                                                    |
| Mars to <i>limit</i> ( $\oplus\varphi$ ) . . . . .                    | 1.8460                        |                                                                    |
| <i>Limit</i> ( $\oplus\varphi$ ) to the Aphelion of Mercury . . . . . | 1.8598                        |                                                                    |
| Aphelion of Mercury }<br>to <i>limit</i> within                       | 1.8736                        |                                                                    |

The mean of these is 1.8253; differing a little less than  $\frac{1}{8}$ th of itself from either extreme.

From these we have for the *exterior* half-planet intervals:—

| <i>Region.</i>                              | <i>Factor <math>r\frac{3}{2}</math>.</i> |
|---------------------------------------------|------------------------------------------|
| Neptune to Uranus . . . . .                 | 1.5369 —                                 |
| Mars to Earth . . . . .                     | 1.5710 —                                 |
| Aphelion to Perihelion of Mercury . . . . . | 1.6014 +                                 |

For the *interior* half-planet intervals, we have:—

| <i>Region.</i>                     | <i>Factor <math>r\frac{1}{2}</math>.</i> |
|------------------------------------|------------------------------------------|
| Uranus to $\hat{\circ}i$ . . . . . | 1.3356 +                                 |
| Earth to Venus . . . . .           | 1.3612 +                                 |

From the *interior* half-planet Venus to Mercury

$$r = 1.8632 +$$

Under these conditions the value of the *half-planet limit*  $\hat{\circ}i$ , *i.e.* interior to Uranus, may now be determined; and it will be found to be 14.64275.<sup>1</sup>

(14) The arrangement of the planetary system in accordance with all that has now been determined, is similar to that of the *Second Approximate Arrangement* heretofore exhibited, (10); the value of the *interior* half-planet limit  $\hat{\circ}i$  and the standard value<sup>2</sup> of the asteroid limit (A) being both inserted; and besides the column of differences of Law from Fact in terms of the Earth's mean distance as 1, we have

would then approach more nearly to the standard value of limit (A). In this aspect of the matter, the difference of limit (A) from the mean in question would seem to be *on the right side*.

If, however, we take the mean between the two extremes of the known distances, that of Flora 2.20336, and that of Sylvia 3.49411 (as Prof. Kirkwood has done—*Proceed. of Royal Ast. Soc.*, vol. xxix. p. 99), we shall have the value 2.84873; which is almost exactly the same with the value of (A) here brought out.

<sup>1</sup> What ought to be the *mass* of the missing half-planet cannot be ascertained without the introduction of *theoretical* considerations; of which more hereafter.

<sup>2</sup> As exhibited in *Article* (12).

an additional column expressing in every case the same difference in terms of the quantity to be compared, which is  $a'$ , the planet's own mean distance from the Sun, or else  $d'$ , the distance from the Sun of the *limit* in question.

Thus, for example, in the instance of Saturn, Law—Fact = 0.094 of the Earth's mean distance; and *that*, in the next column, is seen to be only 0.010 of Saturn's own mean distance from the Sun.

COMPLETED ARRANGEMENT OF THE PLANETARY SYSTEM, EXHIBITING THE CORRESPONDENCE OF LAW WITH FACT.  
TABLE (B).

The coincidences between Law and Fact, as compared with previous approximations, are now far more complete. The greatest actual difference is that in the instance of Uranus, which, after all, on the large scale of that planet's orbit is less than  $\frac{1}{50}$ th of the quantity to be measured.<sup>1</sup>

The distances of Mercury in aphelion and in perihelion as stated in the column of Fact are themselves computed from Mercury's mean distance and the eccentricity of his orbit, *at the present date*. With other values of the eccentricity, we would have had as follows:—

| Eccentricity.                    | Aph. Dist. | L.—F      | Per. Dist. | L.—F.     |
|----------------------------------|------------|-----------|------------|-----------|
| Maximum <sup>2</sup> = 0.2317185 | 0.47680    | - 0.019 + | 0.29740    | - 0.012 - |
| Mean = 0.1766064                 | 0.45546    | + 0.002 + | 0.31873    | - 0.033   |
| Minimum <sup>2</sup> = 0.1214943 | 0.43413    | + 0.023 + | 0.34007    | - 0.054 + |

<sup>1</sup> Why, after all, Uranus seems to have, as it were, *fallen in* from his appropriate position, may be considered in another connexion; not here, where only the relations themselves are permitted to have place, without the introduction of any physical hypothesis to explain them, as was indeed intimated in the first part of this Section. The same may be said of Mars.

<sup>2</sup> The maximum and minimum values of the eccentricity here inserted, are those given by John N. Stockwell, M.A., in his Memoir on the Secular Variations of the Elements of the Orbits of Eight Principal Planets, Introduction, p. xi.—*Smithsonian Contributions to Knowledge*, vol. xviii.

## SATELLITE SYSTEMS.

## SYSTEM OF SATURN.

(15) In the System of Saturn we find again three ratios; all of them fractional powers of one another, and one of these, like the special one in the Planetary System, *the square root* of another.

The rings, both bright and dusky, have also *their* places in the satellite series, with the condition always understood, that the distance of any ring from Saturn's centre is to be measured from that ring's *own centre of gyration*.

(16) Now the *centre of gyration* of an indefinitely thin ring, and one which has, in effect, a uniform density and thinness, this centre, has *itself* special relations which it will be well to notice.

For let  $R$  be the radius of the outer edge of the ring,  $C$  the distance of the centre of gyration from Saturn's centre (or from the common centre of all the circles in question), and  $r$  the radius of the inner edge of the ring.

Then, we have

$$C = \sqrt{\frac{R^4 - r^4}{2R^2 - 2r^2}}.$$

or,

$$C = \sqrt{\frac{1}{2} \cdot \frac{R^4 - r^4}{R^2 - r^2}}.$$

That is

$$C = \sqrt{\frac{1}{2} \cdot \frac{(R^2 + r^2)(R^2 - r^2)}{R^2 - r^2}};$$

or

$$C = \sqrt{\frac{1}{2}(R^2 + r^2)} \dots (A).$$

But now, if the ring be supposed to be *so* divided by the circumference of a circle concentric with the edges of the ring, that the two portions thus obtained shall be *equal in area*, and the radius of this bisecting circumference be  $x$ ; then the expressions for the two portions of the ring will be equivalent to one another, and so we shall have

$$\begin{aligned} \pi(R^2 - x^2) &= \pi(x^2 - r^2); \text{ whence} \\ R^2 - x^2 &= x^2 - r^2; \text{ and} \\ R^2 + r^2 &= 2x^2; \text{ whence} \\ x^2 &= \frac{1}{2}(R^2 + r^2); \text{ and} \\ x &= \sqrt{\frac{1}{2}(R^2 + r^2)} \dots (B). \end{aligned}$$

<sup>1</sup> Dr. Olinthus Gregory's Mechanics, 4th edition, Art. 312, Ex. III.

The value of  $x$  in equation (B) is the same with that of  $C$  in equation (A). Hence

$$C = x;$$

or the centre of gyration is in the circumference of a circle concentric with the edges of the ring, and bisecting its area.

And a cylindrical surface having this bisecting circle for one of its edges, and cutting perpendicularly through a ring formed like that of Saturn, would (density uniform) also bisect the volume of the ring, and also would bisect the material of the ring; and the value of  $C$ , the centre of gyration of this ring of sensible thickness, would not be affected by these new circumstances; the indefinitely thin ring being the plane of rotation on which the other might be projected.<sup>1</sup>

(17) The equation for the centre of gyration of any two equal masses will take the same form as that of *Eq.* (B), with the condition, however, that  $R$  and  $r$  shall respectively denote the radii of gyration of those masses. Indicating these radii then by  $R'$  and  $r'$ , and the masses (equivalent or not) by  $M$  and  $m$ ; and then (since velocities are as radii of simultaneous rotation) the general formula will be thus expressed:—

$$C = \sqrt{\frac{MR^2 + mr'^2}{M + m}} \dots\dots (C);$$

which, when  $M = m$ , is reduced to

$$C = \sqrt{\frac{1}{2}(R^2 + r'^2)} \dots\dots (C),$$

so that when the equivalent masses are both rings, the one wholly clasping the other, like the two halves of the ring in question, the position of the centre of gyration may be obtained by a similar process, whether the  $\frac{1}{2}$  sum of the squares under the radicle be that of those quantities representing the radii of outer and inner perimeters of the whole ring, as in *Eq.* (A); or the radii of gyration of the respective halves, as in *Eq.* (C).

---

<sup>1</sup> This property of the centre of gyration of a ring like those of Saturn, as well as of the indefinitely thin ring, has about it a species of mathematical elegance. I know not whether the enunciation of it is new; but the correspondence of the position assigned by it with that of the division between the bright ring systems of Saturn, is a curious, if not an interesting one. [See *Article* (19).]

## SYSTEM OF SATURN.

| Dusky Ring,    | } $r'$ } $r'$               | { 1.3811  | { 1.3402<br>1.3588 | { + 0.04 +<br>+ 0.02 + } |

In the instance of the Dusky Ring two values appear in the column of Fact; the first of these indicating the position of the centre of gyration, if the Dusky Ring have an interval between it and the inner Bright Ring (proportional, perhaps, on a smaller scale, to that which exists between the two systems of Bright Rings). The second value is that which obtains, if we suppose the Dusky Ring to extend quite up to the Bright Ring. The difference between the results is but a small fraction of the quantity to be compared.

[In view of the very considerable number of limits in the upper region of the system at which no satellite is found, and the ratios themselves being so small, it might almost seem that the approximate coincidence between Law and Fact was a forced one, brought about by a special arrangement and combination of terms. But not merely the number of terms (or ratios, or their equivalent) is indispensable,

but the right order of their grouping must also be measurably maintained, to bring about the coincidences in their appropriate places. Then, afterward, from Dione downward, every limit has its corresponding satellite or ring, with the bare exception of that between the satellites and the rings. Then the discrepancy between Law and Fact is, in most cases, all but insensible. The most conspicuous deviation is that in the instance of the more recently discovered satellite Hyperion, the distance of which is not yet well determined. Another fact seems also not without its significance; viz., that the two ratios in the region of the rings have the same value,  $r'$ .<sup>1</sup>

The somewhat abnormal deviation from Law in the instance of *Hyperion*, presents a case like those of *Uranus* (especially) and, also, *Mars*, in the planetary system;<sup>2</sup> the resemblance being all the more accurate because the difference from Law is, in all these instances, *negative*. These, and other peculiarities, will be reviewed in the aspect of theory, in Section III.

*Other Relations.*

(19) The centre of gyration of the whole system of Bright Rings is at the distance from Saturn's centre = 1.9090; being just within the outer edge of the inner Bright Ring (or Rings) which is at the distance 1.9276.

In the subordinate system of the two outer Bright Rings the ratio of their distances (2.1825 — and 2.0522 —) = 1.06438; while  $r^{\frac{1}{4}}$  = 1.06423.

Manifestly, then, the arrangement of the *Outer System* of Bright Rings is

$$\left. \begin{array}{l} \text{Exterior Ring} \\ \text{Interior Ring} \end{array} \right\} r^{\frac{1}{4}}, \text{ agreeing well with } \left\{ \begin{array}{l} \text{Fact.} \\ 2.1825 - \\ 2.0522 - \end{array} \right\}^3$$

SYSTEM OF JUPITER.

TABLE (D).

(20). *Definite Arrangement of the System.*

| SATELLITES. | LAW.     | RATIO.                       | FACT.         | L.—F.     |           |
|-------------|----------|------------------------------|---------------|-----------|-----------|
| IV.         | 26.99835 | $r = (1.6007)^{\frac{6}{5}}$ | 26.99835      | 0.000     |           |
| III.        | 15.35202 |                              | 15.35024      | + 0.002 — |           |
| II.         | 9.62147  |                              | $r' = 1.5956$ | 9.62347   | — 0.002   |
| I.          | 6.04934  |                              | $r' = 1.5905$ | 6.04853   | + 0.001 — |

Here  $r = r^{\frac{6}{5}}$ , or  $r' = r^{\frac{5}{6}}$ ; and the value of  $r'$  regularly *diminishes* by 0.0051.

<sup>1</sup> The accepted values in the column of Fact agree very closely with the very careful deductions of Capt. Jacob, from his own observations (*Memoirs of the Royal Astronomical Society*, vol. xxviii. p. 108). These are referred to Titan's distance as the standard; and when measured by Saturn's eq. radius give for

|                  |           |        |                    |
|------------------|-----------|--------|--------------------|
| <i>Rhea</i>      | . . . . . | 9.5562 | instead of 9.5528. |
| <i>Dione</i>     | . . . . . | 6.8445 | “ “ 6.8398.        |
| <i>Tethys</i>    | . . . . . | 5.3470 | “ “ 5.3396.        |
| <i>Enceladus</i> | . . . . . | 4.3207 | “ “ 4.3125.        |

<sup>2</sup> See Note 1 to (14).

<sup>3</sup> Of these relations, and what else is connected with them, more hereafter in Section III.

## SYSTEM OF URANUS.

TABLE (E).

(21) *Approximate Arrangement.*

| Satellites.       | Mean Distance from Planet. | Ratios.                           |
|-------------------|----------------------------|-----------------------------------|
| Oberon . . . . .  | 22.56                      | 1.3333                            |
| Titania . . . . . | 16.92                      | $(1.3913)^{\frac{2}{3}} = 1.6411$ |
| Umbriel . . . . . | 10.32                      | 1.3932                            |
| Ariel . . . . .   | 7.40                       |                                   |

Here  $r = r'^{\frac{2}{3}}$ , or  $r' = r^{\frac{3}{2}}$ ; and the value of  $r'$  *increases*; as  $r$  did (but regularly) in the planetary system.

*Summing up of Relations of Mean Distances from their Respective Centres.*

(22) In the *Planetary System* the value of the leading ratio  $r$  is at first 1.7770, and the regularly progressive *increase* of its value afterwards, from term to term = 0.0138. Also  $r' = r^{\frac{3}{2}}$ ; and  $r'' = r^{\frac{3}{2}}$ .

In the *System of Saturn*  $r = 1.28273$ ,  $r' = r^{\frac{3}{2}}$ , and  $r'' = r^{\frac{3}{2}}$ ; and all the ratios are *constant*. Moreover, for the two outermost rings,  $r''' = r^{\frac{3}{2}} = (r')^{\frac{1}{2}}$ .

In the *System of Jupiter* we have  $r' = r^{\frac{3}{2}}$ ;  $r'$ , at first, = 1.6007; and the regularly progressive *decrease* of its value = 0.0051.

In the *System of Uranus*  $r' = r^{\frac{3}{2}}$ ; and the value of  $r'$  shows an *increase* from term to term.

*Additional Feature of Resemblance of Two Half-Planets.*

(23) The inclination of the equator of *Venus* to the plane of that planet's orbit, does not seem to have been accurately determined, but it is usually stated to be nearly  $72^{\circ}$ ; the rotation of the planet (as is usually the case) being direct.

In the *Monthly Notices of the Royal Astronomical Society*, vol. xxiii. p. 166 (Jan. 1873), *W. Buffham, Esq.*, as a merely approximate result as yet, makes the inclination of the equator of Uranus  $80^{\circ}$ .<sup>1</sup> "Movement direct."

The orbits of the satellites are inclined to the ecliptic at an angle of about  $79^{\circ}$ ; and *their* motion is *retrograde*.

These two half-planets, then, though near to the two extremes of the system, are again alike; viz., in the great inclinations of their equators, as well as in the direction of their rotations.

<sup>1</sup> Inclination, viz., to the plane of the ecliptic. The inclination to the plane of the planet's own orbit is about  $79\frac{1}{2}^{\circ}$ .

## SECTION III.

## APPLICATION OF THEORETICAL CONSIDERATIONS AND THE DEVELOPMENT OF OTHER RELATIONS.

(24) The further discussion of the relations exhibited in Section II. will be aided, and circumlocution, at the same time, avoided, by the introduction of considerations having reference to the *Nebular Hypothesis of Laplace*; and this especially in the exposition of other relations, the investigation of which was prompted by suggestions furnished by the application of this very hypothesis somewhat extended and modified, in a manner now to be specified.

In the exposition of his hypothesis, its illustrious author supposes the atmosphere of the *rotating Sun* to have extended, in ancient times, to the limit (or, when at the furthest, very near to the limit) at which the centrifugal force of rotation must have balanced the force of attraction.

That afterwards—the atmosphere shrinking from loss of heat—the rotation (for reasons which he specifies) would be accelerated as the atmospheric molecules drew nearer to the centre of the Sun,<sup>1</sup> and, that the limit in the plane of the Sun's equator, at which the two forces—centripetal and centrifugal—would balance one another, would, therefore, be found further and further in.<sup>2</sup>

That thus successively, at new limits *in the plane of the Sun's equator*, further and further inward, the centrifugal and centripetal forces would indeed balance one another; insomuch that the *thin and narrow zones* thus *in equilibrio* in the plane of the equator (they having no tendency either to fall in or to be thrown off), would themselves be “abandoned” by the atmosphere in its farther shrinkage.<sup>3</sup>

(25) The description then goes on to state that the same equilibrium of forces *not* existing with respect to the atmospheric molecules situated on the *parallels* to

Fig. 2.

<sup>1</sup> The loss of heat will not affect the moment of rotation—the *turning power*—and every molecule (because of the shrinkage) having a shorter circuit, will accomplish it in *less time*. Then also, as shown hereafter, there will be some acceleration of the *actual velocity*. The original phraseology, as it were, anticipates this also, and provides for both. “La rotation doit être plus prompte, quand ces molécules se rapprochent du centre du soleil.”—*Exposition du Système du Monde*. Note VII

<sup>2</sup> The centrifugal force, in accordance with its law, increasing at a more rapid rate than the attractive force; the centrifugal force (with conservation of areas) varying inversely as the cube of the distance, instead of inversely as the square of the distance, so that, at a distance *a little within* the atmospheric limit, and at which the attractive force was still somewhat *in excess*, it would soon happen that a small increase of both forces (from the shrinkage of the material) would result in increasing the centrifugal force so much more rapidly as to exhaust the difference of the two forces, and leave the nebulous material ready to be “abandoned.”

<sup>3</sup> Very different this, from the supposition of many misinformed persons, that the rings here spoken of were *thrown off* by an excess of centrifugal force.

the solar equator, these molecules would, by their attraction, be brought closer to the atmosphere, in the progress of its condensation, and would not cease to belong

Fig. 3.

to it until, in consequence of this motion, they were brought nearer to the plane of the equator.<sup>1</sup>

(26) The description proceeds, saying of these "zones of vapor" (or rather nebulous zones) successively abandoned, that these zones, must, in all probability, form by their condensation and the mutual

attraction of their molecules, diverse concentric nebulous rings circulating around the Sun. The mutual friction of the molecules of every ring must accelerate some

and retard others, until all had acquired the same angular motion. And (when all this went round together) the actual velocity of molecules further from the centre would be greater than that of those nearer; the parts near the outside of the ring going *uniformly* round in a large circuit, in the *same time* in which those nearer, also moving *uniformly*, described a smaller circuit. Thus, with time the same, the angle  $ACB$  being the same for both, the part, such as  $AB$ , is greater than the similar part  $ab$  of the smaller circuit;<sup>2</sup> and the *part* of  $AB$  described in a unit (say a second) of time, greater than the similar part of  $ab$ ; *i. e.* the *actual velocity* in  $AB$  is *greater*.

(27) Besides all this, in the progress *inward* of the particles forming the nebulous rings, the *actual velocity of rotation* of those particles would be *increased* conformably to the principle of the conservation of areas; which requires that an area such as  $ACB$ , in the figure, should *continue* to be passed over, by the rotation of  $CB$ , in the *same time*; so that if  $AC$  and  $BC$  be shortened, the figure must be *broader* to preserve its size, or the distance  $BA$ , traversed in the *same time* must be *greater* than before; *i. e.* the particle must move *faster* along  $BA$ ; while the particles attracted toward the others *outward*, and then forming the inner part of the ring, would, in obedience to the same principle, have *their* actual velocity of rotation *diminished*.

(28) Then if all the molecules of the nebulous ring continued to condense without being disunited, they would at length form a liquid or a solid ring.<sup>3</sup> But the regularity requisite in such a case, in every part of the ring and also in its cooling, must make this a very rare phenomenon. Accordingly the solar system affords but a single example of this kind—that of the rings of Saturn.

<sup>1</sup> The diagrams are our own. M. Laplace employs none in his Exposition du Système du Monde.

<sup>2</sup> The difference being =  $Bc$ .

<sup>3</sup> Or a ring of small solids closely arranged, as seems to be actually true of the rings of Saturn.

(29) But almost always, the nebulous ring must have broken into several masses, which, moving with velocities but slightly different, would continue to circulate at the same distance from the sun.

These masses would take a spheroidal form with a motion of rotation in the direction of their motion of revolution (from west to east), because of the inferior molecules (26), having less actual velocity than the superior; and thus would soon be formed so many nebulous planets. But if one of these were sufficiently powerful to bring together successively, by its attraction, all the others about its centre, the nebulous ring would then be transformed into a single nebulous spheroidal mass revolving around the sun, and having a rotation in the direction of its revolution. This last has been the most common case; though the solar system, nevertheless, furnishes an example of the first case, in the small planets which revolve between Mars and Jupiter, at least if we do not suppose with Olbers that they primitively formed a single planet, which a powerful explosion divided into several parts animated with different velocities.

(30) Now if we follow the changes which an ulterior cooling would produce in the nebulous planets of which we have come to conceive the formation, we shall see form, at the centre of each, a nucleus incessantly increasing by the condensation of its surrounding atmosphere.

(31) In this state the planet would perfectly resemble the sun in the nebulous state in which we considered it. The process of cooling must then produce, at different limits in its atmosphere, phenomena similar to those which we have described; that is to say, rings and satellites circulating around its centre in the direction of the planet's own rotation, and turning at the same time (the satellites that is) upon themselves. The regular distribution of the mass of the rings of Saturn about its centre, and in the plane of its equator, results naturally from this hypothesis, and without it becomes inexplicable. "The rings" (exclaims the framer of the hypothesis) "appear to me to be an ever-present proof of the primitive extension of the atmosphere of Saturn, and of its successive retreats."<sup>1</sup>

(32) He then proceeds to say that the singular phenomena of the small eccentricity of the orbits of the planets and the satellites, of the small inclination of those orbits to the solar equator, of the identity of direction of rotation and revolution of all<sup>2</sup>

<sup>1</sup> "Me paraissent être des preuves toujours subsistantes de l'extension primitive de l'atmosphère de Saturn, et de ses retraites successives."

<sup>2</sup> Difference of density, etc. might cause the rotation of a satellite in a rare case to be in a contrary direction, as is true of the orbital motion of the satellites of Uranus.

these bodies with that of the rotation of the sun, flow from the hypothesis which he proposes, and give to it great probability.<sup>1</sup>

(33) If the solar system had been formed with perfect regularity, the orbits of the bodies which compose it would have been circles, the planes of which, as well as those of their several equators and rings, would have coincided with the plane of the solar equator. But we may conceive that the innumerable varieties which must exist in the temperature and density of the different parts of those great masses, have produced the eccentricities of their orbits, and the deviation of their motions from the plane of that equator.

(34) The author then goes on to show that, on this hypothesis, the comets are strangers to the system, formed by the condensation of nebulous matter elsewhere, but drawn in when they come into the region in which the attraction of the sun is predominant; and he then proceeds further to show that this will account for all the peculiarities of their motion, as well as the variety in the inclinations of their orbits.

(35) M. Laplace then adds that, if in the zones abandoned by the atmosphere of the sun there were found molecules too volatile to unite to one another, or to the planets, they ought, while continuing to circulate around the sun, to present all the appearances of the Zodiacal Light, without opposing sensible resistance to the several bodies of the planetary system, either because of their extreme rarity, or because their motion is the same with that of the planets themselves.

(36) In all that has now been stated, which, for the most part, is a translation, or else a paraphrase of M. Laplace's *Note VII.* to his *Exposition du Système du Monde*, in all this, there has been no allusion to the operation of another cause, which may well have produced changes in the nebulous material, antecedent to those which have been already contemplated. The solar atmosphere, when at its largest extent, must also have had a very oblate form, and the portions near to the pole of the rotating sun, because of the superior density, and close proximity of the sun's body, have been subjected to an attractive force greatly superior to that prevalent (or barely in equilibrio) in the equatorial regions.

(37) Now a greater attractive force acting on nebulous matter increases the local density where the force is thus urgent; as is manifest from what we observe in the nuclei of comets. But a greater density of the same sort of material is accompanied by a *more profuse radiation of heat*. All this could not fail to produce changes in the actual, as well as angular, velocity of the portions thus affected, which would not conform to the changes of both, then going on, in the regions nearer to, or at the equator.<sup>2</sup> A *rending* of the material of the atmosphere must thus result, perpetuating itself all round the sun, so long as the portions most affected were not detached to the extent of "abandonment."

There might still be a tendency in the portions thus separated by the rent from those parts still closely attached, to preserve, at least rudely, an approximation, even in their exterior surface, to the spheroidal form; the situation, at any given distance from the axis—when once that situation has been attained—presenting the same ratio there of centripetal and centrifugal forces; since, in so far as density

<sup>1</sup> Verisimilitude rather—"vraisemblance."

<sup>2</sup> To say nothing of the *molecular* changes which might be superinduced by the condensation itself.

is concerned, the centrifugal force at the extremity of the radius of rotation, would be as the density, and the attractive force, still acting at the same angle with the plane of the parallel, be also as the density, so that the element of density being, in effect, all but excluded from the comparison, there would remain very nearly the same ratio of the forces as before; so that the not yet "abandoned" portion of the atmosphere would scarcely have its exterior spheroidal form affected.<sup>1</sup>

And, although the case is not *just the same*, divisions into something like *spheroidal shells* resembling those here supposed may be<sup>2</sup> traced in the representations of the heads of comets, among others that of 1680, as represented in Plate VI. of the third volume of *Delambre's Astronomie Théorique et Pratique*; the same being copied from the *Histoire Céleste of Lemonnier*. The appearance in question is yet more conspicuous in the representations of the head of the great comet of 1858, given by Prof. G. P. Bond, in Vol. III. of the *Annals of the Observatory of Harvard College*. A very faithful copy of one of these is here given.

Fig. 6.

(38) Now, the partially condensed *shell* thus formed (if indeed admissible) must itself have exerted a *conservative power* in preventing the too frequent occurrence of cases like that of the asteroids; viz., by an earlier holding together of the greater number of the "abandoned" equatorial portions of the atmosphere in the process tending to form rings or planets.<sup>3</sup>

Nay, it might even be questioned whether the more dense portions of the atmosphere, earlier separated, may not in their progress toward the equatorial plane, described in (25), have arrived at the state of equilibrium of the forces, before the equatorial portions were ready for the same; and so, *the formation of a planet have gone on thus far, from a shell instead of a ring.*

Just one change more, to be followed by its consequences, might then have taken place. The more dense portions, being the *first* about to be "abandoned," might be found to be further *outward* than the rarer equatorial portions; and attaching the latter to themselves by the attraction due to a greater density.

(39) Now, the special arrangements of the two half-planets, Earth and Venus, are *as though* what has here been discussed and explained, were entirely applicable to them.

<sup>1</sup> Though the ellipticity of the same might be appreciably changed.

<sup>2</sup> Which may indeed, in part, be consequent on the changes adverted to in *Note 2*, on p. 20.

<sup>3</sup> The oblate form of the spheroid here alluded to; the more profuse radiation of heat due to a greater condensation of the nebulous material in the polar region; and the division of the envelope into shells were all insisted upon by the author of this paper in a communication made by him to the American Association for the Advancement of Science, at their meeting in Montreal, in 1857. The idea of a more profuse radiation of heat from the polar regions seems, since that date, to have independently occurred to others; and a profound and thorough investigation of the form of the oblate solar spheroid and its variations, as also of the density of the solar atmosphere, at the various planetary distances, the relative breadth of the rings, etc., though without reference in that connexion to a more profuse polar radiation, is given by David Trowbridge, A.M., in vol. xxxviii. (Second Series) of the *American Journal of Science and the Arts*, Nov. 1864.

*Specialities of the Half-Planets Earth and Venus.*

1. In accordance with the immediately preceding conclusion, the *exterior* half-planet, the Earth, not merely shows a density greater than that of its interior half-planet Venus, but also, as seen in Table (A), in (3), a density altogether remarkable in view of the Earth's place in the planetary system.

2. The inclination of the equator of Venus to the plane of that planet's orbit (from  $73^\circ$  to  $75^\circ$ , most probably) presents a marked contrast to what we find in the cases of Mercury, the Earth, and Mars, in all which the inclination of the equator approaches to a mean value that is nearly the same with the obliquity of our equator to the ecliptic; and this, while a like contrast does not exist in the respect of the time of rotation (the sidereal day) of Venus; for that is nearly the same with each of the respective sidereal days of these same other three planets, in this region of the system. But the inclination of the equator of Venus is, up to the present time, without a parallel in all the system, except in the instance of another *half-planet*, viz. Uranus.<sup>1</sup>

And here the state of things is, withal, *as though* the enormous deviation of the plane of the equator from the plane of the planet's own orbit (and which implies also a very large deviation from the plane of the sun's equator) were itself *due to the attraction* towards the more dense outer portion, already commented on, which went to the formation of the Earth; an attraction acting in a direction nearly *perpendicular* to the half-planet's first-forming equator and its parallels.

Thus the material, at its first rolling up from the form of a ring or shell, would be inclined to rotate in the plane of *EW*, but being drawn outward by the attraction of the more dense material in the direction *EN*, the resultant rotation would be in a direction such as *EO*, as represented in the figure at 1, and transferred to the position marked 2.

Fig. 7.

All this might begin antecedently to the process of rending which introduced the formation of half-planets, or perhaps go on during that very process; in which

<sup>1</sup> During the *revolution* of a whole ring or shell around the sun, every part of the outside would be presented *once* in its turn to the entire circuit of the heavens; and so in effect would *rotate once* around a point within that ring or shell. This would determine the angular velocity of rotation at the first gathering up to form a planet. The existence of more dense material outside would seem *not* to have superinduced a *retrograde* rotation in this case; but to have interfered to the preventing of an *accelerated* rotation, and thus the *more dense* material be kept *outside*, until, in the contest of forces, the rending into two half-planet masses took place. The existing state of things, in its various aspects, seems to look toward this; but the problem is too complicated a one to justify an assertion that such was the succession of events.

same process of rending, the attraction of material outward, *i. e.*, toward the more dense Earth-forming mass, may itself have been efficient.<sup>1</sup>

3. The division of material into two half-planet portions, would very probably take place, at what, with reference to the revolution around the sun, was the *centre* (or rather the central line) of gyration of the whole mass (at the distance *SC* in the figure); leaving the material on the one side and the other of that limit, to be gathered into the half-planet masses, each around its own special centre of gyration (at *C'* and *C''*); which special centre would be that due to the *half-planet itself*, when formed.

Making use, then, of the half-planets themselves (gathered at *C'* and *C''*),<sup>2</sup> and finding *their* centre of gyration, we shall approximate to the former position of (*C*) the centre of gyration of the whole mass. But *that* would be the position of the *whole* planet, if the material had all gone to form it, *i. e.*, the *limit* ( $\oplus\varphi$ ) in Table (B), so that the centre of gyration of the two half-planets should be found very near to the limit ( $\oplus\varphi$ ) in Table (B), in (14).

Fig. 8.

Now—with the masses of the Earth and of Venus as given in Table (A), in (3), and their distances as given in the column of Law in Table (B) in (14)—from Eq. C in (17), we have for the distance from the sun of the centre of gyration of the Earth and Venus,

$$\begin{array}{l} \text{with sun's horizontal parallax} = 8''.848, C = 0.88665 \\ \text{" " " " " = 8.78, C = 0.88579.} \end{array}$$

And the position due to the *whole* planetary limit ( $\oplus\varphi$ ) in Table (B), in accordance with Law 1st (10), is

$$(\oplus\varphi) = 0.85101.$$

4. But the separation of the material into two half-planet portions would, withal, take place at the limit where the attractive forces of the forming half-planets were in equilibrio; on one side of which limit the material would be gathered (by the excess of attractive force on *that* side) in the formation of a half-planet toward *that* side; and on the other side of (the neutral) limit, in the formation of another

<sup>1</sup> A writer in the *Westminster Review*, vol. lxx. (July, 1858), has introduced the idea of a greatly inclined rotation in a *thick* ring, or even a retrograde rotation; but he has applied it in a region of the system in which the conditions which he introduces are misplaced. A different explanation is applicable in the instance of Uranus, as will be shown hereafter.

<sup>2</sup> Which will scarcely differ, in either case, from the very centre of the planet itself.

half-planet on that *other* side [as they are represented in Fig. 8], gathering around  $C'$ ,  $C''$ , the one on the one side, and the other on the other side of  $CD$ , the dividing limit of neutrality, where the forces being equivalent and opposed would be in equilibrio. It would seem then to be desirable to ascertain whether the limit *thus* defined will agree with either, or nearly with both, of the other two determinations already made.

Fig. 9.

Now when two planets ( $P$  and  $P'$ ) are in conjunction, as seen from the sun (at  $S$ ), the position of the point ( $N$ ), at which their attractions would be equivalent and opposite, and so neutralize one another, may be found, as is well known, by so dividing the distance ( $PP'$ ) between those planets, that

$$\frac{NP}{NP'} = \frac{\sqrt{\text{of mass of } P'}}{\sqrt{\text{of mass of } P}}^1$$

Fig. 10.

But, in the act of the rending described in the *Note* on p. 22, portions such as  $Q$  and  $Q'$  would act on one another directly (in the line  $QQ'$ ) very much as would two small planets; and so the neutral point ( $N$ ) be determined as before, viz. :—

$$\frac{QN}{Q'N} = \frac{\sqrt{\text{of mass of } Q'}}{\sqrt{\text{of mass of } Q}}$$

And the local oblique action of neighboring portions would conform to very nearly the same ratio; so that the whole action within distances at which it would be appreciable would have its neutral limit ( $N'NN''$ ) dividing the distance between the points of reference of rupturing annular masses in a manner approximating to that which obtains in the case of two planets. And what is here stated of them, might also be asserted of the sections of shells, parallel to the equatorial rings, with approximately the same result as to the dividing limit.

Making use then, as heretofore, of the half-planets themselves, as accumulated around what were their respective points of reference, while yet their masses were

<sup>1</sup> The point  $N$  is one of the limits of Prof. Kirkwood's spheres of attraction, made use of in his Analogy.

in the former state; we shall, by the application of the equation here adopted, in effect obtain  $QN$  or  $Q'N$ , and hence also  $SN$ , the distance of the neutral point  $N$  from the sun's centre. With the same data from Tables (A) and (B) in (3) and in (14), as before, we shall then have

$$\begin{array}{l} \text{with the sun's horizontal parallax } 8''.8448, \quad SN = 0.85383, \\ \text{and with " " " " } 8.78, \quad SN = 0.85459. \end{array} \left. \vphantom{\begin{array}{l} SN = 0.85383, \\ SN = 0.85459. \end{array}} \right\}$$

While, (14), limit  $(\oplus \varphi)$  due to a whole planet distance in Table (B), is . . . . . 0.85101,

exhibiting all but a perfect coincidence; while, as before, the distance of the centre of

$$\text{gyration from the sun's centre . . . } SC = \left\{ \begin{array}{l} 0.88665, \text{ or } \\ 0.88579, \end{array} \right\}$$

(40) Summing up then the specialities of the two half-planets, Earth and Venus, which are consistent with the theoretical considerations now exhibited, we have

1. In accordance with the conclusion in (39), the greater density of the *exterior* half-planet, the Earth.

2. The *tilting up* (if the expression be allowable) of the equator of Venus and its parallels—as if by the attraction outward, due to that same greater density—in the antecedent arrangement of the half-planet masses.

3 and 4. The decided approximation to agreement in position of—

- (a) The whole planet limit  $(\oplus \varphi)$  in Table (B).
- (b) The neutral point, or point of equal attraction between the two half-planet masses, and
- (c) The distance from the sun's centre of the centre of gyration of the same two half-planet masses, thus—

$$\begin{array}{l} (\oplus \varphi) = 0.851 + \\ \text{Neutral position is at } 0.854 \pm \\ \text{Centre of gyration is at } 0.886 \pm \end{array}$$

*Determination of the Mass due to a Half-Planet  $\delta_i$  (now missing), interior to Uranus.*

(41) The distance due to such a half-planet has already been determined in accordance with *Law 3d*, (10), and the same is recorded in Table (B), in (14).

The *mass* of this half-planet may be determined by means of the equation for the centre of gyration of it and Uranus; the case being similar to that of the Earth and Venus,<sup>1</sup> and the whole planet limit here being *limit* ( $\upsilon$ ), in Table (B).

Now let  $a'$  represent the mean distance of Uranus from the sun, and  $m'$  the mass of that planet; while  $a$  and  $m$ , respectively, represent like quantities in the instance of  $\delta_i$ . Then, as limit ( $\upsilon$ ) represents the position due to the centre of gyration, *Eq. (c)* of (17), will read

<sup>1</sup> But here the agreement of the position of the centre of gyration with the whole planet limit, will have this favoring condition; that under the less stringent circumstances, in this region of the planetary system, it is not probable that any considerable portion of the more dense material was carried to the *outside*, in the half-planet formation (or the tendency to it), as, (39), seemed to have been true in the instance of the Earth.

$$(U) = \sqrt{\frac{m'.a'^2 + m.a^2}{m + m'}}; \text{ or}$$

$$(U)^2 = \frac{m'.a'^2 + m.a^2}{m + m'}; \text{ whence}$$

$$m(U)^2 + m'(U)^2 = m'.a'^2 + m.a^2; \text{ and}$$

$$m \left\{ (U)^2 - a^2 \right\} = m' \left\{ a'^2 - (U)^2 \right\}; \text{ and}$$

$$m = \frac{a'^2 - (U)^2}{(U)^2 - a^2} \times m'; \text{ or}$$

$$m = \frac{a' + (U) \times (a' - (U))}{(U) + a \times (U) - a} \times m';$$

which, as  $a'$ ,  $(U)$ , and  $a$  are all determined, will give us  $m$  in terms of  $m'$ .

Substituting, then, the values of  $a'$ ,  $(U)$ , and  $a$ , as found in the column of  $Luv$  in Table (B), in (14), we have

$$m = (1.38865) m',$$

*i. e.*, the mass of  $\textcircled{i}$  = (1.38865) of the mass of *Uranus*; or, substituting the value of the latter, as found in Table (A), in (3), we shall have

$$\text{Mass of } \textcircled{i} = \frac{1}{15845} = 0.00006312 - \text{ of the mass of the sun.}$$

*The most probable Answer to the Question—What has become of the Missing Mass?*

(42) The most ready reply to this question would seem to be—that the missing mass had, (29), been formed into a group of *asteroids*. But then, as this region of the planetary system is one in which large masses abound, it would also seem that the mass of a group of *asteroids* here, might reasonably be supposed to be very considerable, even if the computation already made, (41), had not indicated this very mass to be almost  $1\frac{4}{10}$  that of *Uranus*.

And if these considerations are conceded to have weight, the existence of the seemingly missing mass, in the form of a group of *asteroids*, becomes at once inadmissible; since, if such a group were there, its existence would speedily be evidenced by the perturbations of both *Uranus* and *Saturn*, which such a group would produce.

(43) Rejecting, then, the hypothesis of the existence of a group of *asteroids* in this region, the next hypothesis which it may be found to be appropriate to consider will be, whether, in the accumulation of the great mass which was to constitute *Saturn*, the material which would have formed the *interior* half-planet  $\textcircled{i}$  was not *itself drawn over and inward by the overmastering attraction of the Saturn-forming mass*, which thus *attached to itself* the interior half-planet mass rent away from *Uranus*.

In favor of this hypothesis we shall find *ten special consistencies*, which in their turn will *introduce others*, having *more extended relations*.

## 1.

The *mass* of the forming Saturn would be *adequate* to the exercise in its own place of the o'ermastering attraction here supposed.

For if from the mass of Saturn, as found in Table (A) in (3); viz.:—

$$\frac{1}{3501.6} = 0.00028558 +,$$

we subtract the mass of  $\textcircled{i}$   $\quad\quad\quad = 0.00006312 +,$

as computed in (41), there will remain  $\quad\quad\quad 0.00022246 +,$

for the mass of the forming Saturn; *before* the mass due to the interior half-planet  $\textcircled{i}$ , had been drawn over and inward to unite with the other portion of the entire mass which has gone to constitute the complete Saturn system as we now have it.

Now as the symbol for Saturn is  $\textcircled{h}$ , we may represent this first *formative portion* of that planet's mass [which we just now found to be = 0.00022246 +] by the symbol  $\textcircled{h}$ . And then computing the position of the point of equal attraction, or neutral point [as, heretofore, (39), in the case of Earth and Venus], we shall find  $\textcircled{h}$ 's attraction to extend in the direction of Uranus, to the distance from the sun's centre = to 16.40924, which is far beyond the distance due to the (missing) interior half-planet  $\textcircled{i}$  (viz., 14.64275) as found in Table (B), in (14). The attractive force of the pre-existing Saturn-mass was, then, adequate *in measure* to the effect here supposed.

## 2.

But this same limit, 16.40924, to which the attractive force of  $\textcircled{h}$  extended, in the direction of Uranus, this, also, is not so *very far short* of the limit (U),<sup>1</sup> *i. e.*, 16.91431, at which the whole planet mass would be likely to be rent to form the two half-planets, Uranus and  $\textcircled{i}$ ; it being, *in that respect*, a limit analogous to that found to be a dividing limit in the case of Earth and Venus in which *both* the half-planets *still exist*

## 3.

The very great inclination of the satellite system of Uranus to the plane of the planet's orbit was, long ago, determined by Sir William Herschel; the inclination of the orbits of the satellites to the plane of the ecliptic being nearly  $79^\circ$ ; and the inclination to the plane of the orbit of Uranus must therefore be nearly  $79^\circ 1'$ ,<sup>2</sup> while their ascending nodes on the ecliptic are nearly in longitude  $166\frac{1}{2}^\circ$ ; *motion retrograde*.

And, again, the recent observations, (23), of W. Buffham, Esq., detailed in the *Monthly Notices of the Royal Astronomical Society*, vol. xxxiii., No. 3 (Jan. 1873), lead to results at present stated by him to be "the merest approximations;"<sup>3</sup> but which yet give

<sup>1</sup> In Table (B), in (14).

<sup>2</sup> Or  $100^\circ 59'$ ; the motion being *retrograde*.

|                                                 |                    |
|-------------------------------------------------|--------------------|
| Long. of the asc. node of the equator . . . . . | 110°               |
| Inclination of the equator . . . . .            | 80°                |
| Time of rotation . . . . .                      | 12 <sup>h</sup> ±; |

*motion direct.*

From these several data, it would seem probable that the equator is inclined about  $79\frac{1}{3}^\circ$  to the plane of the planet's orbit, and some  $60^\circ$  to the orbits of the satellites.

So that the drawing over of material (*inward* now, and not outward) due to the proximity of the great mass of  $\hat{\kappa}_2$ , would seem to have produced in the direction of the plane of the equator of Uranus, an alteration like that which, as heretofore shown, (39), seems to have taken place in the instance of another half-planet, Venus; the tilting-up (if the expression may again be tolerated) being quite as great in this instance as in the other; and here the orbits of the satellites are also enormously displaced.

#### 4.

In the instance of Venus, it would seem that the great inclination of the equatorial plane was, (39), brought about by the attractive force of the Earth-mass of greater density; but, in the present instance, the like effect, as already shown, seems to have been due to proximity of the great mass of  $\hat{\kappa}_2$ ; though, (3), the density of the existing planet Saturn, as exhibited in Table (A), is the least in the whole planetary system.

But even that is here found to be a fact in place. For the drawing over, (41), of a mass nearly equal to  $1\frac{4}{10}$  of that of Uranus, from a region in which the mean density of the nebulous material was far inferior to that of the  $\hat{\kappa}_2$ -mass,<sup>1</sup> could hardly fail to have resulted in a mean density of the existing Saturn, such as we find.

#### 5.

The scrupulously exact coincidence of the numbers in the column of *Law* with those in the column of *Fact* in Table (B), in (14), approaches the nearest to an exception, in the very instance of Uranus; the existing Uranus being 0.374 of the Earth's distance within the distance due to Uranus in accordance with *Law 2d*, in (10); though even that difference is less than  $\frac{1}{50}$ th of the whole distance of Uranus itself. But this, if we give it any weight at all, is, again, a fact in place. Uranus in the drawing over of the material towards  $\hat{\kappa}_2$ , may, perhaps, have somewhat fallen in.

#### 6.

The acquisition of so much additional material, drawn in from a great distance, must, it would seem, have the effect of giving to the condensing Saturn-mass a much more oblate form than that which would otherwise have pertained to it; which seems to be confirmed by the fact that the outermost satellite is at the dis-

<sup>1</sup> For the probable ratio of the densities here in question, see the paper of Mr. Trowbridge already referred to in the *Note* to (38).

tance of more than 64 radii of Saturn from his centre; while the distance of the outermost satellite of Jupiter, measured in the same way, is scarcely 27 radii of its primary.

And the *comparatively feeble light* of this same outermost satellite of Saturn is withal consistent with a *low density* of that satellite;<sup>1</sup> a fact also *in place*, in view of the acquisition of a less dense material from the planetary region *exterior* to the ancient Saturn  $\hat{\text{h}}$ : the outermost satellite, in the view of the hypothesis as to its formation, being most probably constituted of the portion the least dense of all.

## 7.

Such being the special form and constitution of the Saturn-forming mass—the formation of the extensive system of satellites might have been nearly completed, *in advance of the “abandonment” of the material* which now constitutes *Saturn’s rings*,<sup>2</sup> or that satellite formation, at least have gone so far, as to *keep the rings in their form and general arrangement*, while Saturn, condensing, shrank away from the rings, yet with his central position with regard to them (or rather their corresponding arrangement around him) preserved; *the conservative power* of the satellites, in these respects, being exerted in those very ancient times, even as now.<sup>3</sup>

It was then, it would seem, the drawing over and inward of the material which else had constituted the half-planet between Saturn and Uranus, that, as has been said, gave to Saturn and to his system the special form and arrangements that rendered the retaining of the rings *as rings* a possibility; which has made them an actuality; made Saturn what the author of the *Novum Organum* would term an “*instantia solitaria*,” in the solar system.

## 8.

The same processes of the transference and combination of material here insisted upon, seem also to have affected the *inclination of Saturn’s own equator*, and that of *almost the whole Saturnian System, to the plane of the planet’s orbit*.

For this great planet’s equator, and his rings, and the orbits of his satellites<sup>4</sup> are inclined at an angle of more than 28° with the plane of his orbit; while the inclination of Jupiter’s equator, and that of the orbits of three of his satellites, does not much differ from 3°.

## 9.

Another relation may possibly have some significance in this connexion; viz., the ratio of the *periodic time* of the interior half-planet  $\hat{\text{c}}$  to the periodic time of the ancient Saturn  $\hat{\text{h}}$ .

<sup>1</sup> Not that the phenomenon of a comparatively feeble light would absolutely *require* the supposition of a low density; but, as stated, the one thing would be consistent with the other.

<sup>2</sup> There being material for that so *far outward* in the direction of the plane of the equator of the very oblate spheroid, or near to that; the spheroid being made so very oblate *by the acquisition from without of the material of  $\hat{\text{c}}$* .

<sup>3</sup> For “no planet can have a ring, unless it is surrounded by a sufficient number of properly-arranged satellites. *Saturn* seems to be the only planet which is in this category; and it is the only one, therefore, which could sustain a ring.”—Prof. Peirce, On the Constitution of Saturn’s Ring, in the *Astronomical Journal* No 27, p. 18.

<sup>4</sup> All but that of the outer one.

For the mean distance from the sun of the (now missing) interior half-planet  $\textcircled{S}i$ , and that of Saturn [as recorded in the column of *Law* in Table (B), in (14)] being, respectively, 14.64275 and 9.44511, the application of Kepler's 3d Law will give us the corresponding periodic times; and then the measurement of the greater of these by the less, will show the periodic time due to the half-planet  $\textcircled{S}i$  to be to the periodic time of the ancient Saturn  $\textcircled{S}i$  at its theoretical distance, in the ratio of 1.9303 to 1; and a still more scrupulous determination of the data in question than that exhibited in Table (B), might, perhaps, show the ratio to be very accurately that of 2 to 1.<sup>1</sup>

But with this ratio existing, the perturbations of one of the masses by the other at their nearest approach (intensified, it may be, by eccentricity of form or of orbit; or otherwise) would *recur* after *every two* subsequent revolutions of the ancient Saturn  $\textcircled{S}i$ ; and very possibly the effect of those perturbations become, in this way, *cumulative*; and thus the passing over of the material of the half-planet have been furthered and aided, until its mass was absorbed by the ancient Saturn  $\textcircled{S}i$ .<sup>2</sup>

## 10.

It is not inconsistent with all that has just now been stated, that the term for the distance of Saturn reported in the column of *Law* in Table (B) is *less* than the corresponding term in the column of *Fact*; the ancient Saturn  $\textcircled{S}i$  having, as it were, been *drawn outward* in the completion of the catastrophe of the absorption of  $\textcircled{S}i$ ; while Uranus, as indicated in Consistency 5 of this series, may, perhaps, have somewhat *fallen in*.

## 11.

The (additional) 11th of these consistencies has much more extensive relations; some of which will here be exhibited and explained; they being especially such as are comprehended under the following title:—

*The more Ancient Arrangement of the Material of the Planetary System.*

For if—*always adhering to the hypothesis that the material of the existing Saturn was increased in the way so often already specified*—we endeavor to show what was the *more ancient combination and arrangement of the material of the solar system* (viz., ere the rending and the rupture, of which we now seem to find traces, were, in all their extent, accomplished), we shall find that, by regarding the masses in question (*half-planets, Asteroid mass or masses, etc.*), as recombined about their respective centres of gyration, and then ascertaining the *positions* of those centres, to serve as our points of reference, we shall thus obtain *a new and fully justified series of terms*, in which, very much as in the other instances of leading ratios in the planetary, and also in the satellite systems, every term will have a ratio to the next

<sup>1</sup> The distance of  $\textcircled{S}i$  being, as stated, 14.64275; then, to perfectly justify a ratio of the periodic times of 2 to 1, would require the distance of the ancient Saturn  $\textcircled{S}i$  to be 9.24562 instead of 9.44511.

<sup>2</sup> [For a further discussion and application of what is here intimated; as well as that of what more the relation in question may be significant, see *Articles* (64) to (67) inclusive.]

succeeding term, which will, here, *decrease* very slowly, but regularly, in the progress inward.

(44) With respect, then, to this recombination—

The value of the 1st, or *Neptune-term* of the series, closely corresponds to that in Table (B) of the completed arrangement of the Planetary System in (14).

For the *2d term* of the series—

|                            |   |                                                                                                                                                                                                                                                                                             |   |                                                                                                                                                                                                                                                        |
|----------------------------|---|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Double Planet Arrangement. | { | Whole planet mass (U).                                                                                                                                                                                                                                                                      | { | (a). The mass of Saturn being reduced to that of $\hat{\eta}$ —to furnish the material for the half-planet $\hat{\delta}i$ —that half-planet must then be regarded as being restored to its appropriate place [as the same is exhibited in Table (B)]. |
|                            |   | (b). The two half-planets, Uranus and $\hat{\delta}i$ , must then be regarded as combined around their centre of gyration to form the <i>whole-planet mass</i> (U).                                                                                                                         |   |                                                                                                                                                                                                                                                        |
|                            |   | Whole planet mass $\hat{\eta}$ .                                                                                                                                                                                                                                                            | { | The mass of $\hat{\eta}$ will then be left at a <i>whole-planet distance</i> .                                                                                                                                                                         |
|                            |   | Then, (c).—The <i>whole planet mass</i> (U), accumulated anew (as already indicated), must be combined with the mass $\hat{\eta}$ to form from both, around <i>their</i> centre of gyration, a quasi <i>double-planet mass</i> [(U) $\hat{\eta}$ ]; to furnish the <i>2d term</i> required. |   |                                                                                                                                                                                                                                                        |

JUPITER will itself, in its mean distance from the sun, furnish the *3d term*.

*Mars* and the *Asteroid mass* (A) will, in the quasi *double-planet* arrangement, at their centre of gyration, furnish the *4th term*; designated as that of [ $\mathcal{J}$  (A)].<sup>1</sup>

The *Earth* and *Venus*, now existing as separate *half-planets*, will, in a *whole-planet* arrangement, furnish (at their *centre of gyration*) the *5th term* very near, (39), to the already recognized limit ( $\oplus \varphi$ ). This *5th term* is then designated as that of [ $\oplus \varphi$ ].

MERCURY, in its mean distance from the sun, furnishes the *6th term*.<sup>2</sup>

<sup>1</sup> In the computation of this 4th term, such a value has, of necessity, been attributed to the asteroid-mass as would make that 4th term in the column of Fact, absolutely the same with the corresponding term in the column of Law. But the value of the asteroid-mass thus determined, is confirmed in a way which cannot but be regarded as extraordinary. [See *Article* (46).]

<sup>2</sup> Neither the *aphelion* nor the *perihelion* distance appearing; though the one is found at a *whole-planet distance*, and the other at an *exterior half-planet distance*, in Table (B), in (14). Mercury, then, at a distance the mean of these two (but in another arrangement) has thus characteristics approaching to those of a *double-planet* [as was intimated, though not explained in (9)]; and this with an appropriate place in the series in which the *double-planet* arrangement appears; the difference between this and the otherwise analogous terms of the arrangement being, that whereas, in the other cases, the material of the two planetary bodies (with reference to its more ancient state) is regarded as accumulated anew, and, as it were, in some measure, reconstructed about the centre of gyration of those bodies; the actual combination, in an analogous position, seems to be found in the *existing planet*, Mercury itself.

The conditions prevalent in this series (with a quasi double-planet arrangement for every *alternate* term), require that the mean ratio  $R_1$  should nearly  $=r^{\frac{2}{3}}$ ,  $r$  being the mean leading ratio for the *whole-planet* arrangement in Table (B), in (14).<sup>1</sup> Accordingly we find that, with the mean value of  $r$ , in Table (B), [which, (13),  $=1.8253$ ], that  $r^{\frac{2}{3}}=2.4660+$ , while the mean value of  $R_1$  prevalent in this new series, is 2.4021.

(45) The whole arrangement, in accordance with what has now been stated, is exhibited in the following table; the symbols of mode of connexion, and dependence, etc., being similar to those in Table (B), in (14).

TABLE (F).

*More Ancient State and Arrangements of the Planetary System.*

| NAMES, etc.                                                | SYMBOLS.                                            | LAW.                | FACT AND DERIVATIONS.        | Diff. L.—F. | Diff. in terms of quantity measured. |         |

| Asteroid mass (A) }<br>Mars .....                          | [♁ (A)]                                             | (2.15051)           | (2.15051)                    | .....       | .....                                |         |
|                                                            |                                                     |                     | Earth..... }<br>Venus..... } | [⊕ ♀]       | 0.89780 $\frac{1}{2}$                | 0.88665 |
| MERCURY.....                                               | ♁                                                   | 0.37589             | 0.38710                      |             |                                      |         |

The values of the ratio  $R_1$ , which determine the numbers in the column of Law, are—

|                            |           |              |                |
|----------------------------|-----------|--------------|----------------|
|                            |           | <i>Diff.</i> |                |
| Ψ to [(U) ♂ <sub>2</sub> ] | . . . . . | 2.4157       | } Mean 2.4021. |
| [(U) ♂ <sub>2</sub> ] to ♃ | . . . . . | 2.4089       |                |
| ♃ to [♁ (A)]               | . . . . . | 2.4021       |                |
| [♁ (A)] to [⊕ ♀]           | . . . . . | 2.3953       |                |
| [⊕ ♀] to ♁                 | . . . . . | 2.3885       |                |

The mean value of  $R_1$  is, then, very nearly 2.4 $\frac{4}{5}$  which  $=\frac{24}{10}=\frac{12}{5}$ , so that every

<sup>1</sup> It being among those conditions that the *centre of gyration* of the component masses should very closely correspond in its position with that due to the intermediate term in the quasi *double-planet series*; a fact which itself seems to indicate, that the law of apportionment of the masses is not independent of that of the distances, but that the one (in the mathematical sense of the term) is a *function* of the other.

term, after the first, is  $\frac{5}{12} \pm$  of that which immediately precedes it; instead of  $\frac{5}{9} \pm$ , which is the whole planet ratio in the existing planetary system.<sup>1</sup>

Now, it is especially to be again observed, that the 2d term of the series in this Table, in the way in which it is here obtained, *supposes*, and it *depends* upon the supposition, that the material of the missing half-planet  $\textcircled{8}i$  passed over and was combined with the other portion of the Saturn-forming mass, to, thus, construct the existing planet Saturn; and it is, (44), by supposing that process *reversed*—*restoring*  $\textcircled{8}i$  to its place—and then *combining* in the way already indicated, (44), that the 2d term of the Table is obtained for the column of Fact, and can, consistently and accurately, occupy its place in the series;<sup>2</sup> so that *this 11th consistency*, supporting the hypothesis of the disappearance of the missing planet, in consequence of its mass having been drawn inward and combined with the Saturn-forming mass, has even more extended relations than the others.

---

Having, then, as far as may be, answered the question, (41), *What has become of the missing mass*, it may next be well to consider what more we may be taught by certain other relations exhibited in Table (F).

*Mass of the Asteroids.*

(46) With the term [ $\textcircled{8}(A)$ ], [at the centre of gyration of Mars and the Asteroid mass (A), as found in Table (F), in (45)], and also with the mass of Mars taken as unity, and the mean distances, from the sun, of Mars and (A), respectively, in Table (B), in (14), we may determine  $m'$ , the Asteroid-mass which will be required to justify the term [ $\textcircled{8}(A)$ ] in Table (F); the case being similar to that of the *interior* half-planet  $\textcircled{8}i$  in (41); except that the value of  $m'$ , the *exterior* mass, is here required instead of  $m$ .

Substituting in the equation, in (41), the values here indicated, we shall find  $m'$ , the *Asteroid-mass*, = 0.58929 of the mass of Mars.

This, with the mass of Mars, as in Table (A), in (3), [=  $\frac{1}{3200\frac{1}{3}000}$ ], will make the *mass of the asteroids* =  $\frac{1}{543\frac{1}{3}14}$  of the mass of the sun.

(47) Now M. Le Verrier, in the *Comptes Rendus*, tome lxxv, p. 880 (Nov. 25,

---

<sup>1</sup> As  $R_1$  here approximates to  $r_1^2$  [ $r$  being the ratio for the whole-planet terms in Table (B)],  $R_1$  will also, incidentally, express very nearly the ratio of the *periodic times* due to the whole-planet distances. Accordingly we find that the ratio of the periodic time of Saturn to that of Jupiter = 2.4697; while the nearly corresponding value of  $R_1$ , as stated in (45), is, as near as may be, 2.4089.

<sup>2</sup> Not only so, but if *leaving out the hypothesis here in question*, we attempt to form the 2d term of the series with the Saturn-mass as it exists, we shall, of course, *fail*; since the placing of so large a portion of the same masses so much *farther inward*, will, at once, displace the centre of gyration in the same direction, and so make the term too small. And the same effect would even be manifest, if we might suppose a group of asteroids to exist in this region; but that, (42), is inadmissible.

On the first of these two suppositions, the centre of gyration would be displaced quite the whole of the Earth's distance from the Sun [being at 11.35 instead of 12.40]; and if the second supposition were admissible, the displacement would be nearly  $\frac{1}{2}$  that distance [being at 11.96 instead of 12.40].

1867) has given us the following equation, dependent on the necessity of an admitted increase in the motion of the perihelion of Mars.

He states that, in so far as we now know—

Ten times the correction of the mass of the Earth, *plus* three times the mass of the small planets, in a mean distance reference of the group, would make a sum equal to 1.38; the mass of the Earth deduced from the parallax of Encke, 8".58, being taken for unity.<sup>1</sup> This mass is  $\frac{1}{354936}$ .

The mass of Mars which M. Le Verrier employed in his investigations, would seem to be the same with that which he has, provisionally, attributed to that planet in the *Comptes Rendus* for July 22, 1872; viz, 0.000000333 of the sun.

With these values of the data, the equation of M. Le Verrier will give us, FOR THE ASTEROID MASS, THE SAME FRACTION OF THE MASS OF MARS WITH THAT WHICH JUSTIFIES THE TERM [ $\delta$ (A)] IN OUR TABLE (F); *if we make* THE SOLAR PARALLAX 8".896;<sup>2</sup> which is a value included within the present limits of uncertainty, and near to the mean of all the more recent determinations.

(48) If, then, fortified by these several coincidences, we allow any weight to the determination of the value of the *Asteroid mass* derived from the justification of the term [ $\delta$ (A)] of the series here in question; it may be noted that this value, (41), depends on the ratio of the difference of the squares of the terms [ $\delta$ (A)] and Mars to the difference of the squares of (A) and [ $\delta$ (A)]; and the tabular values of the quantities represented in the terms thus involved, may all be considered as being approximately well-determined.

[It will, moreover, be observed that the several independent elements which have entered into the computation of this result are:—

1. The leading ratio  $r$ , in Table (B), in (14).
2. The leading ratio  $R_1$ , in Table (F), in (45).
3. The application of the formula *for the centre of gyration*; and

<sup>1</sup> . . . "on doit dire que dix fois la correction de la masse de la Terre, plus trois fois la masse de l'ensemble des petites planètes distribuées en moyenne, d'après ce qu'on en sait aujourd'hui, doit faire une somme égale à 1.38; l'unité étant la masse admise pour la Terre quand on la déduit de la parallaxe d'Encke, 8".58."

<sup>2</sup> For,  $\left(\frac{8''.896}{8''.58}\right)^3 = \frac{\text{increased mass of Earth, } M}{1}$ ; the mass due to parallax 8".58, being = 1

M being thus determined—

Then  $M - 1 = \text{increment of Earth's mass} = i$ .

Then  $m'$  being *asteroid mass*, M. Le Verrier's equation gives—

$$19i + 3m' = 1.38; \text{ whence}$$

$$3m' = 1.38 - 19i, \text{ and}$$

$$\text{asteroid mass, } m' = \frac{1.38 - 19i}{3}; \text{ the mass of the Earth due to parallax}$$

8".58 being 1.

Then  $\frac{1}{354936} m' = \text{asteroid mass } m'' \text{ in terms of the Sun's mass } 1$ .

And this last value is *our* fraction (0.58929) of *M. Le Verrier's mass of Mars*, i.e. the same fraction of the mass of Mars (taken = 1), which justifies the value of our [ $\delta$ (A)] term in our Table (F).

4. The mass of Mars itself, deduced from the mutual action of it and those of the other planets.]

But the value of the same *Asteroid-mass*, as derived from M. Le Verrier's equation, depends on  $\frac{1}{3}$  of *ten times* the excess above 1 of  $\left(\frac{8''.896}{8''.58}\right)^3$ . This value, then, albeit that it wholly depends on ascertained facts for its data, is, nevertheless, very *sensitive* to any, the smallest, change in the value of the solar parallax.

[In a subsequent Memoir on the Masses of the Planets and the Parallax of the Sun, in the *Comptes Rendus*, for July 22, 1872, M. Le Verrier, as the result of a discussion of the *secular variations* of the elements of the orbits of *Mercury*, *Venus*, the *Earth*, *Mars*, and *Jupiter*, states that it is probable that the attraction of the minor planets amounts, up to the present time to a quantity which may be neglected.<sup>1</sup>]

(49) The value of the Asteroid-mass, which we have thus obtained, is, as far as may be, confirmed by yet another consistency.

For with this value of the mass, at distance (A) in the column of *Law* in Table (B), and other masses and distances in Tables (A) and (B), [(3) and (14)], we shall find that the neutral point, or point of equal attraction of this same mass, is, on the side of Jupiter, at the distance 3.16559 from the sun. And the similar limit, on the side of Mars, is at the distance from the sun = 2.13869.

These numbers at once suggest the limits (thus far recognized) of the mean distances of the asteroids.

The supposition of a *half-planet* arrangement of the material in the progress of its early "abandonment" will, however, better provide for all this; as well as exhibit yet other consistencies, as will be shown hereafter.<sup>2</sup>

*Peculiar Relations of the Planet Mercury.*

(50) From Table (B) in (14) and Table (F) in (45), we find that the position and relations of Mercury may be represented as follows:—

|                                            |                                     |  |            |                         |   |                                 |
|--------------------------------------------|-------------------------------------|--|------------|-------------------------|---|---------------------------------|
| Limit or term . . . . .                    | Table (B).                          |  | Table (F). | [⊕☿]                    | } | R <sub>1</sub> = r <sup>2</sup> |
| Whole planet ratio, r                      | { (⊕☿) . . . . .                    |  | . . . . .  |                         |   |                                 |
|                                            | { Aphelion of Mercury } . . . . .   |  | . . . . .  |                         |   |                                 |
| $\frac{1}{2}$ planet ratio, r <sup>2</sup> | { Perihelion of Mercury } . . . . . |  | . . . . .  | (at mean dist.) MERCURY |   |                                 |

so that Mercury, when *in aphelion*, is in the position due to a *whole-planet*; and when *in perihelion* his distance is that due to a *half planet*.

<sup>1</sup> As quoted in the translation of W. T. Lynn, B. A., in the *Monthly Notices of the Proceedings of the Royal Astronomical Society*, vol xxxii., No. 9, p. 323.

<sup>2</sup> See *Articles* (60) and (108).

Then, at his *mean distance* (half-way between the two) his place is that of an *almost double-planet*, in the special arrangement in Table (F).

Of these it may be said:—

1.

That these several peculiarities seem, at once, *to be reconciled and explained* by the supposition that the condensing material (ring, or shell, etc.) which was in position to have formed a whole planet at the *aphelion distance*, and another portion of the condensing material (ring, or shell, etc.) which was in position to have formed what we have termed an *exterior half-planet*, at the *perihelion distance*, have been *combined* to form the existing planet; which, thus, is made up of a *whole-planet mass* and a *half-planet mass*.

2.

But all this *accounts for and explains in mode and in measure*, the VERY GREAT ECCENTRICITY OF THE ORBIT OF MERCURY; his perihelion distance not *extending beyond* the centre (or a point near the centre) of gyration of the half-planet mass (ring, or shell, etc.) due there; and his aphelion distance, *reaching out* to the centre of gyration, or near it, of the whole planet mass due *there*.

*Mass and Distance of a possible Planet interior to Mercury.*

(51) The position of the perihelion of Mercury has, (14), been shown to be that due to an *exterior half-planet*. Hence the distance from the sun of the next planet interior to Mercury may, most probably, be ascertained by dividing the term value of Mercury's perihelion distance, in the colum of *Law* in Table (B), in (14), by the value of  $r^{\frac{1}{2}}$ , in accordance with *Law 3d*, in (10).

The value of  $r^{\frac{1}{2}}$ , for this region of the system, is 1.3733.

Performing then the division thus indicated, we shall have the distance from the sun of the planet interior to Mercury—

$$\varkappa_i = 0.20836.^1$$

We may also ascertain the *whole-planet* position next to that due to the *aphelion* of Mercury, by dividing the aphelion term in the column of *Law* in Table (B), in (14), by the value of  $r$ , in accordance with *Law 1st* in (10).

The value of  $r$ , for this region of the system, is 1.8736. Dividing the value of the *aphelion limit* by that number, will give for the *whole-planet limit* interior to Mercury's aphelion distance, the value 0.24422 + .

Thus, then, we shall have the following arrangement:—

$$\begin{array}{l} r^{\frac{3}{2}} \left\{ \begin{array}{l} \dots \dots \text{(Whole planet limit) aph. distance} \dots \dots 0.45758 \\ \text{(Exterior } \frac{1}{2} \text{ planet-limit) per. distance} \dots \dots 0.28573 \end{array} \right\} r \\ r^{\frac{1}{2}} \left\{ \begin{array}{l} \dots \dots \text{whole planet limit} \dots \dots \dots 0.24422 \\ \text{Interior half-planet } \varkappa_i \dots \dots \dots 0.20836 \end{array} \right\} \end{array}$$

---

<sup>1</sup> This is very accurately the distance required (by *Kepler's 3d Law*) to justify the periodic time of the so-called "planet Vulcan," as the same has recently been ascertained by Prof. Kirkwood, on the hypothesis, that the appearances of certain solar spots were due to the transits of such a body.

Then for the *mass* of the *interior* half-planet  $\mathfrak{z}i$ , we need first to redistribute the material of Mercury, so as to place its *whole-planet portion* at the aphelion, and its *half-planet portion* at the perihelion; to come back to the forming state, etc., described and exhibited in symbol in (50).

Putting then the whole mass of Mercury = to 1; if that be so distributed to the aphelion and perihelion positions, that *the centre of gyration* of the distributed portions shall be found at Mercury's *mean distance*,<sup>1</sup> we shall have—

$$\begin{array}{l} 0.5617245 \text{ of Mercury's mass, for the aphelion, and} \\ 0.4382755 \text{ " " " " " perihelion.} \end{array}$$

The values *thus* far requisite having been ascertained, the case is but a repetition of that of the *mass* of  $\mathfrak{e}i$  in (41); and by substituting the values now before us, and reducing, we shall find the value of the *mass* of the *interior* half-planet—  
*m* of  $\mathfrak{z}i$ , interior to Mercury, = 0.594059 of the *mass* of Mercury.

(52) Now M. Le Verrier, in the *Comptes Rendus*, tome XLIX. p. 382, (Sept. 1859), speaking of a cause adequate to produce an ascertained secular motion of 38" in the perihelion of Mercury, admits the supposition of a hypothetical planet, situated between Mercury and the Sun, and says that, as the hypothetical planet ought to impress on the perihelion of Mercury a secular motion of 38 seconds, the resulting relation between its (the planet's) mass and its distance from the sun will be such that, in measure, as we suppose the distance less, the mass will be increased, and the converse: and he adds, that, "For a distance a little less than the half of the mean distance of Mercury from the Sun, the mass sought would be equal to that of Mercury."

The mass which, *on our own plan, in the following out of our own hypothesis*, (51), we have found for the hypothetical planet is 0.594059 of the *mass* of Mercury; and when, in conjunction with Mercury, as seen from the sun, the distance between the two planets [see (51) and Table (A), in (3)], would be

$$0.38710 - 0.20836 = 0.17874;$$

and "a mass equal to that of Mercury," *similarly situated*, would have the same attractive force with that due to our hypothetical planet, at a distance, for that mass, inside of Mercury = to 0.23190, *i. e.*, a distance from the sun = 0.15520; which is indeed, assuredly, somewhat "less than the half of the mean distance of Mercury from the Sun," which  $\frac{1}{2}$  distance, accurately, = 0.19355.

<sup>1</sup> For this purpose,  $m+m'$ , the sum of the two masses, being put = to 1;  $m'=1-m$ .

Also—since the ratios of the distances are known, or may be readily ascertained—if (C) be the distance of the centre of gyration, and the distance of the outer body =  $q$  (C), and that of the inner =  $p$  (C); then, substituting in *Eq.* (C) in (17), and reducing, we shall have, for the fraction of the whole mass pertaining to the inner body,

$$m = \frac{q^2 - 1}{q^2 - p^2};$$

which will, also by substitution and subtraction, give us  $m'$ , since it =  $1 - m$ .

All this, *so far*, approximates to an accordance with M. Le Verrier's required action of the mass in question. It is then sufficiently manifest that our hypothetical planet, as to *mass and distance both*, would be such as measurably to satisfy the conditions of the ascertained perturbation; and so we need not pursue the investigation of a troublesome problem any farther.

*Peculiar Relations of the Living Force of (simultaneous) Rotation of some of the Planetary and Satellite Masses.*

(53) If Jupiter and Saturn should (or if they did) turn around the sun, *in the same time*; the moment of rotation must, in the instance of either, be represented by the formula, *mass*  $\times$  (*velocity*)<sup>2</sup>; or, as velocity in this case would be, as *a*, the radius vector of rotation, the *ratio* of the moments will be obtained by comparing *mass*  $\times$  (*radius vector*)<sup>2</sup> of the one with *mass*  $\times$  (*radius vector*)<sup>2</sup> of the other. So with *m* and *m'*, respectively, for the masses, and *a* and *a'* for the radii vectores; *i. e.* the mean distances from the sun, as in the column of *Law* in Table (B), in (14), and the masses, as in Table (A), in (3); we have—

$$\text{For Jupiter, } ma^2 = 0.026142.$$

$$\text{For Saturn, } m'a'^2 = 0.025477.$$

or with the distances as in column of *Fact* in Table (B); we have—

$$\text{For Jupiter, } ma^2 = 0.025832.$$

$$\text{For Saturn, } m'a'^2 = 0.025985.$$

The approach to a ratio of equality is here very close.<sup>1</sup>

There is also an approximation to the same state of things in the following cases,<sup>2</sup>

The respective moments of (simultaneous) rotation of  $\hat{\text{h}}$  (*i. e.* Saturn *reduced to its ancient state*), of Uranus, and also of  $\hat{\text{e}}i$  [the half-planet (supplied) *interior to Uranus*], are all nearly equal to one another; the ratios being—

$$\frac{m r^2 \hat{\text{h}}}{m' r'^2 \hat{\text{e}}} = 1.1431 \dots \dots (1).$$

$$\frac{m' r'^2 \hat{\text{e}}}{m'' r''^2 \hat{\text{e}}i} = 1.0060 \dots \dots (2).$$

Then, when the *combined* masses of Saturn and Uranus [in the *More Ancient State*, as exhibited in the term [(U) $\hat{\text{h}}$ ], in Table (F), in (45)], are compared with *Neptune* in respect to the moment of (simultaneous) rotation; we have for the ratio—

<sup>1</sup> This curious relation was first made known by the author of this paper to the *American Association for the Advancement of Science*, at their Meeting in Montreal, in 1857; also the division into shells, etc.

<sup>2</sup> Which might be somewhat varied, were all the masses more accurately determined.

$$\frac{m_1^2 r_1^2 \text{ of } [(U)\hat{h}]}{m^{m_2, m_2} \text{ of } \Psi} = 1.1101 \dots \dots (3)^1$$

Lastly, in the *System of Saturn*,  $m$  being the mass of the outer, and  $m'$  that of the inner bright system of rings; we shall have for the ratio of the moments of (simultaneous) rotation—

$$\frac{m \times a^2 \text{ of outer rings}}{m' \times a'^2 \text{ of inner rings}} = 1.1400 \dots \dots (4);$$

the rings being respectively referred, each to its centre of gyration [obtained as in (16)].

[Then, since the rings in Table (C) in (18), have their places as *satellites*; if the *periodic times* of the rings referred to their centres of gyration agree with *Kepler's 3d Law*, and so actual velocities are as  $a^{\frac{1}{2}}$  to  $a'^{\frac{1}{2}}$ , and hence their 2d powers as  $a$  to  $a'$ ; we shall have for the ratio of the moments of rotation of the existing and turning rings

$$\frac{m' \times a' \text{ of inner rings}}{m \times a \text{ of outer rings}} = 1.0752.]$$

There is a very close resemblance between ratios (1) and (4).<sup>2</sup> Were, then, those *ancient masses* compared in (1), *ring-like in form*; and *did* the masses, with nearly equal moments of (*simultaneous*) rotation, go round the central body together?

If, in an ancient state, they were *parts of the atmospheres of their primary and central body*, in every case; then they *did* go round together. But, whether we admit any part of that hypothesis, or else reject any portion, or all of it; THE RATIOS REMAIN, and seemingly without that hypothesis, they remain unaccounted for.

There is yet another aspect of the matter, and that is—that the rings or shells, etc., separated about the time *when the moments in question became nearly equal*.

*Application of other Conditions appertaining to the ring-like Form. What succeeded these.—Position of great Planets, and of largest Satellites.*

(54) It has, (16), been shown that the centre of gyration of a *homogeneous ring* is in the circumference in which the mass of the ring is bisected; and that thus, we have

$$(C)^2 = \frac{1}{2}(R^2 + r^2)$$

<sup>1</sup> Ratios (2) and (3) are consistent with the supposition in (43), that the material of Saturn was gathered in part from the *interior half-planet*, now missing (the values  $\hat{h}$  and  $\hat{\delta}i$  being dependent on that); but they did not seem to be of such importance as to require their admission as *Coincidence 12th* of the series exhibited in (43) and (45).

<sup>2</sup> Though it should not be overlooked that ratio (4) is that existing in a satellite system, which is here compared with those found in the system of the primary planets.

(C) representing  $\phi R_3$  in the figure, *i. e.* the distance of the centre of gyration from the centre of force, and  $R$  and  $r$ , respectively, the radii of the edges of the ring, so that we have

$$\overline{\phi R_3}^2 = \frac{1}{2}(\overline{\phi R_1}^2 + \overline{\phi R_2}^2).$$

Now the like being also true of the half-rings, with *their* centres of gyration at  $R_2$  and  $R_4$ , respectively; we shall also have

$$\overline{\phi R_2}^2 = \frac{1}{2}(\overline{\phi R_1}^2 + \overline{\phi R_3}^2); \text{ and}$$

$$\overline{\phi R_4}^2 = \frac{1}{2}(\overline{\phi R_3}^2 + \overline{\phi R_5}^2);$$

from which, by substitution and reduction, we shall obtain

$$\overline{\phi R_3}^2 = \frac{1}{2}(\overline{\phi R_2}^2 + \overline{\phi R_4}^2);$$

in which the *centres of gyration of the half-rings* respectively, take the places of the *edges* of the whole ring.

(55) The supposition here throughout has been that all the material was homogeneous. But as the “abandoned” rings, or ring-like masses, would increase in density inward, the centre of gyration for each half-ring, as well as that of the whole ring, would also, therefore, be *within* that assigned by the formula.

Nevertheless it would seem that this would affect, or rather has affected, the several quantities, proportionally.

Accordingly, we find that *the mass* of the system of the inner bright rings of Saturn *is* considerably *greater* than *the mass* of the system of the outer bright rings; yet the other condition here in question is fulfilled.

For the centre of gyration of the outer bright rings, [Table (C) in (18)], is at the distance . . . . . 2.1165.

And the centre of gyration of *both systems* of the bright rings, as obtained independently by the general formula, is at distance . . . 1.9090.

And that of the system of the *inner* bright rings is at . . . . . 1.7097.

Now the sum of the squares of the first and last of these numbers is 7.16399197;

$$\text{and } \frac{1}{2} \text{ of the same} = 3.58199593 +$$

And the square of the intermediate number, 1.9090, = 3.64428100; showing a very close correspondence with the formula.

Accepting, then, this result *an induction*, we shall find, on trial, in the same way, a semblance of a *ring-like* form of the “abandoned” masses, apparent, even in the case of the *Earth* and *Venus*.

For the sum of the squares of their mean distances [as those distances are given in the column of *Law* in Table (B) in (14)] is . . . . . 1.51928

$$\text{and } \frac{1}{2} \text{ sum} = 0.75964$$

And, (C) being distance of the centre of gyration, . . . . . (C)<sup>2</sup> = 0.78616;

in which case ( $C$ )<sup>2</sup> is the greater because of the superior density of the Earth. [And the great relative distance of our own satellite (nearly 60 radii of the Earth) as, in the similar instance in Saturn's system, is also [6 of (43)] indicative of a great oblateness of the nebulous material at some stage of its progress.]

(56) Again, a like relation is found in the case of the mean distance and centre of (simultaneous) gyration of *Uranus* and *Neptune*.

In the instance of these we have an approximation to *equality in the masses*;<sup>1</sup> the ratio of the mass of *Neptune* to that of *Uranus* being

$$\frac{m\Psi}{m'\delta} = 1.11678.$$

Moreover ( $C$ ), the centre of gyration of the two planets is at the distance 25.4457-; and while

$$\begin{aligned} \frac{1}{2}(\text{mean dist. } \Psi)^2 + \frac{1}{2}(\text{mean dist. } \delta)^2 &= 635.704 \\ (C)^2 &= (25.4457-)^2 \dots \dots = 647.481 \end{aligned}$$

This is consistent with a *ring-like* form of the two masses in question, after the "abandonment" of the material of which they were constituted; the flowing over of material in this outer portion of the oblate solar atmosphere having given to the whole, or, at least, to both the parts of the masses in question, a form not unlike that of a thick ring.

Fig. 12.

All this is consistent with that form, yet does not *require* the masses to have had such a form; since, (17), the equation here in question would, accurately, exist in the case of *any equal masses*.

(57) The state of things arrived at (perhaps later) in the case of *Jupiter* and *Saturn*, (53), seems to be inconsistent with a mere ring-like form for both masses; but to be a consequence of the accession of material from regions of the sun's atmosphere extra-equatorial. Accordingly we shall find that the equation here in question does not obtain in that instance.

But under the conditions approximated to in the case of planets exterior to them, and at length attained in the instance of those two great masses, viz.

$$ma^2 = m'a'^2,$$

we have the masses inversely as the squares of the radii of gyration; so that the resulting planets must increase in mass, in the progress inward, until we come to the instance of *Jupiter*, the greatest of all;<sup>2</sup> the ring-like masses, or the shells, though successively decreasing in volume, yet increasing more rapidly in density,

<sup>1</sup> The mass of *Neptune* is the greater; *Uranus* having just possibly lost somewhat in the process, (43), which carried away the mass of the now missing planet.

<sup>2</sup> Mr. Trowbridge, in his investigation already referred to (*Note to 38*), [in 1864], shows that this would be true of the "abandoned" rings. But the increase of the mass of the great planets, in the progress inward, would seem to be too rapid to be explained by *that alone*. The other changes and relations in question may, as it would seem, have been even more efficient; and the *most* of these were indicated by the author of this paper in 1857, as heretofore stated in the *same Note to Article (38)*.

for some distance within; so that the planets of greatest mass would *not* be the *outermost*, but the masses of the successive planets will be greater and greater, so long as the density increases in a greater ratio than that in which the volume diminishes; aided, withal, by the whole-planet arrangement, which supervenes in the Saturn and Jupiter arrangement, and, in the instance of Saturn, (42), by the half-planet acquired.

And this arrangement of the masses we actually find, with some variation in the instance of Uranus.<sup>1</sup>

(58) Closely analogous to this arrangement of the masses in the great planetary system is that which we find in the *System of Saturn*; viz. Japetus outside, for one of the larger satellites, followed by Titan, the Jupiter of the system, with smaller satellites after it (Hyperion *before* it, in the place analogous to that of Uranus), and other satellites, larger than Hyperion, farther inward.

(59) Then too, in the *System of Jupiter*, the relative masses of the satellites are—

|               |   |   |   |   |   |       |
|---------------|---|---|---|---|---|-------|
| Satellite IV. | . | . | . | . | . | 42659 |
| “ III.        | . | . | . | . | . | 88497 |
| “ II.         | . | . | . | . | . | 23235 |
| “ I.          | . | . | . | . | . | 17328 |

so that the mass of Satellite IV. approaches to being more than double that of either Satellite II. or Satellite I.; while the mass of Satellite III. is more than the double of *that* again; the *great* masses *outside* of the others; and yet, as in the other systems, the *greatest of all* not the *outermost*.

#### *Arrangements of the Asteroid-mass.*

(60) The neutral points for the Asteroid-mass, towards *Jupiter* on the one side and *Mars* on the other, have, (49), been already stated. But when we come to apply the formula for the ring-like mass; viz. that which has, (55), been especially in question, we do not succeed. We thus have a *negative* indication that the Asteroid-mass, *as a whole*, did not have a ring-like form.

But if we suppose a *half-planet* arrangement of the mass, we shall have

|                                                    |   |   |   |   |            |
|----------------------------------------------------|---|---|---|---|------------|
| Distance of <i>exterior</i> half-planet            | . | . | . | . | 3.34083    |
| “ “ <i>interior</i> “                              | . | . | . | . | 2.47748    |
| And then the sum of their squares                  | . | . | . | . | 17.29905 + |
| $\frac{1}{2}$ sum                                  | . | . | . | . | 8.64953—   |
| Square of mean distance (A), in Table (B) in (14), | . | . | . | . | 8.28067;   |

again approximating to the requirements of the formula.

|                                                                                                              |   |   |   |   |         |
|--------------------------------------------------------------------------------------------------------------|---|---|---|---|---------|
| The neutral point, or point of equal attraction, between <i>Jupiter</i> and the exterior half-planet will be | . | . | . | . | 3.35790 |
| That between the two half-planets,                                                                           | . | . | . | . | 2.94068 |
| Between the interior half-planet and <i>Mars</i> ,                                                           | . | . | . | . | 2.14438 |

<sup>1</sup> May be in a measure accounted for and explained by the special influences to which, (43), that planet appears to have been subjected.

The first and last of these, toward one limit and the other, also indicate the *range* of the mean distances of the asteroids better than the result in (49). [The middle limit 2.94068 here given, is a little outside of the centre of gyration of the two half-planet masses, which is at whole-planet distance (A) of Table B, = 2.87831—the more dense material being inward: a state of things of which there is a distinct semblance, (19), in the previous example of *Saturn's rings*. In the case of the *Earth* and *Venus*, (39), the centre of gyration is without the neutral point, as it ought to be, because of the superior density of the earth.]

The exterior limit, 3.35790, at which the attraction of the outer mass and that of *Jupiter* would seem to have been in equilibrio, is scarcely 0.017 (of the Earth's mean distance) outside of the position due to the exterior half-planet.<sup>1</sup>

(61) The distances 3.34083 and 2.47748, respectively due to the exterior and interior half-planets, themselves exhibit approximations to the *aphelion* and the *perihelion distances of several of the existing asteroids*; inasmuch that their case in that respect resembles that of *MERCURY*, already commented on in (50): with the marked difference, however, that while the orbit of *MERCURY* is, indeed, limited in its aphelion by a whole-planet distance, and in its perihelion by the succeeding half-planet distance, the existing planet seems to have *combined in itself* the material which would have appertained to both the whole and the half-planet.

(62) The very small mass due to the exterior half-planet (0.4274 of the interior half-planet, or 0.2518 of *Mars*) would itself suggest the probability that but few asteroids were to be looked for at a mean distance, near to the outer limit 3.35790; and the progress of discovery, thus far, has justified such a conclusion.

*Special Relations of the Moments of (simultaneous) Rotation (around the same centre) of the two supposed Asteroid-masses and that of Mars.*

(63) The moments of (simultaneous) rotation of the *two Asteroid-masses (half-planetary in position)* and that of *Mars* have, respectively, the ratio of the following representative numbers:—

|                        |           |         |   |              |
|------------------------|-----------|---------|---|--------------|
| Exterior Asteroid-mass | . . . . . | 2.8108  | } | Mean, 2.4410 |
| Interior “ “           | . . . . . | 2.0712  |   |              |
| <i>Mars</i> . . . . .  | . . . . . | 2.4679. |   |              |

*Of Missing Terms, or, at least, Varieties in Planetary or Satellite Series, other than those heretofore noticed; and the Explanation of the same.—A Resisting Medium.*

(64) As “the comet of *Lexell*” had its orbit *twice* changed, as a special consequence of its periodic time being very nearly  $\frac{1}{2}$  that of *Jupiter*, so that the comet was for the second time brought very near to that disturbing planet after only two revolutions; so, also, it has been well argued that when the periodic time

---

<sup>1</sup> So that, as has often been surmised, the o’ermastering attraction of *Jupiter* must (it would seem) have interfered with the existence of the outer half-planet as such; and this, by an action not very unlike that of *Saturn*, (43), in preventing the continuance of anything like a half-planet interior to *Uranus*.

of the disturbing planet was very nearly a multiple of the periodic time of an "abandoned" ring; very similar effects would follow, which have, in part, at least, been indicated by Prof. Daniel Kirkwood in his paper *On the Nebular Hypothesis and the Approximate Commensurability of Planetary Periods*, in the *Monthly Notices of the Royal Astronomical Society*, vol. xxix. In that paper, at p. 99 of the volume quoted, he sums up, in part, what he had discussed, as follows:—

"A planetary particle at the distance 2.5—in the interval between *Thetis* and *Hestia*—would make precisely three revolutions while *Jupiter* completes one; coming always into conjunction with that planet in the same parts of its path.<sup>1</sup> Consequently its orbit would become more and more eccentric until the particle would unite with others, either interior or exterior, thus forming the nucleus of an asteroid. Even should the disturbed body not come in contact with other matter, the action of *Jupiter* would ultimately change its mean distance, and thus destroy the commensurability of the periodic times. In either case the primitive orbit of the particle would be left destitute of matter.<sup>2</sup> The same reasoning is, of course, applicable to other intervals;" and Prof. Kirkwood produces evidence to show that the "intervals in the asteroid zone"—however small at best—are yet appreciably greater in the instances of "nearly commensurable periods." With respect to the interval between the two *Rings* (or system of rings) of *Saturn*, Prof. Kirkwood, after a discussion of the distances and periodic times in question, concludes, "It is thus seen that the interval occupies precisely the space in which the periods of satellites would be commensurable with those of the four members of the system immediately exterior. As, therefore, the powerful attraction of *Jupiter* produces the observed *gaps* in the asteroid zone, so the *disturbing influence of Saturn's interior satellites is the physical cause of the permanent interval between the two bright rings.*"

Prof. Kirkwood concludes his paper with the declaration that the Nebular Hypothesis . . . . "assigns an obvious cause for the establishment of nuclei in such positions that their periods will be nearly commensurable with that of the disturbing body. As these nuclei would receive accretions of matter from portions of space both interior and exterior to their respective orbits, their distances from the central body, during their planetary growth, would not be liable to great variation."

(65) Now, with our half-planetary arrangement of the Asteroid-mass, (60), the periodic times of *Jupiter*, the *exterior* half-planet mass, the *interior* half-planet mass, and *Mars*, will, respectively, be related as follows; the coincidences, though not absolute, being yet very close—

$$\begin{aligned} \text{P. Time (T) of } \textit{Jupiter} &= 2 \text{ (T) of } \textit{exterior} \textit{ asteroid-mass,} \\ &= 3 \text{ (T) of } \textit{interior} \textit{ asteroid mass; and} \\ \text{(T) of } \textit{interior} \textit{ asteroid-mass} &= 2 \text{ (T) of } \textit{Mars.} \end{aligned}$$

Thus with the action of *Jupiter* on the one side, and *Mars* on the other, there would be abundant occasion for the effects under discussion.

<sup>1</sup> All but the very distance of the *interior* asteroid-mass, as exhibited in (60).

<sup>2</sup> See, again, Consistency 9, in (44); referred in *Note 2*, on p. 30, to this place.

Then also, in view, (62), of the very small *exterior* half-planetary mass, in this instance, and the close approximation of *Jupiter's* o'ermastering influence; and the much larger, (62), *interior* half-planetary mass, and its special relations to *Mars* as here specified, we discern, at last, how the formation of half-planets in this region may have been prevented; also, why the range of the asteroids should be so extensive; why the eccentricity of their orbits should be so great; why so many have been discovered at distances approaching to that of the interior half-planetary mass, and even on the side toward *Mars*; and why so few have been found at distances approaching to that of the *exterior* half-planetary mass.<sup>1</sup>

Besides all this, we have the fact, that the actual distance of *Mars* [as seen in Table (B), in (14)], is appreciably *less* than the distance registered in the column of *Law*; *Mars*, like *Uranus* [see 5 of (43)], having seemingly *fallen in*; though not, like *Uranus*, influenced, to a proportionate extent, by a large planet interior to itself; yet the *acquisition* of sufficient material *from the interior half-planetary mass*, with the inferior velocity of revolution appertaining to that mass, would produce just such an effect.<sup>2</sup>

And the Earth-Venus mass, while it endured (if at all), would have had a periodic time  $\frac{2}{3}$ ths of that of *Mars*; and might, with the other influences in question, contribute to the very considerable *eccentricity* of the orbit of *Mars*;—on which, however, it does not seem to be justifiable to insist.

(66) In the *System of Saturn* there are withal vacuities, (64), in the series of satellites, under the conditions already specified in the other cases. Thus, in the large interval from *Japetus* to *Titan*, if the places for interpolated terms as indicated in Table (C), in (18), be compared with those which would be due to satellites with periodic times *commensurable* with the periodic time of *Japetus*, or with that of *Titan*, we shall have the following results:—

---

<sup>1</sup> Then, among things *supposable*, but not as yet fortified by groups of coincidences, and which *cannot now be used in the way of induction*, are these: If either of the half-planets were after all formed, the oblateness of the nebulous material must have been so great that it might be questioned whether of the two possible forms of a rotating spheroid of equilibrium—the density and the time of rotation being given—the one usually differing but little from a sphere, the other, with the *equatorial diameter enormous* in comparison with the *axis*, the latter might not be the form of the spheroid here produced; it being such as the ring of *Saturn* might become if the body of the planet were removed, and the ring filled up so as to be imperforate. Such a form would be eminently unstable; and if it were broken up, the fragments would *all be small*; as the asteroids indeed are.

Then two such half-planets (with orbits, as has been seen, very eccentric) might all the more readily have realized the ingenious conjecture advanced by Prof. Vaughan at the meeting of the American Association for the Advancement of Science, in 1857; viz. that the asteroids were the fragments resulting from the *collision of two planetary bodies*, in that region of the solar system; thus presenting a new phase of the hypothesis of Olbers.

In the same category, as to not furnishing any induction as yet, may be included the fact that the orbit of Halley's (*retrograde*) comet very nearly (now) intersects that of Phocæa.

<sup>2</sup> For additional proof of a half-planetary arrangement in the Asteroid region, see *Article* (108).

In this region the coincidences, it will be perceived, are more perfect than in the other region exterior to *Titan*.

But it is here, again, worthy of remark, that *Hyperion*, outside of *Titan*, in a place analogous to that of *Uranus* in the planetary system, has, like that planet, *seemingly fallen in somewhat* from its true position in series; as if influenced by the great interior body, under stringent circumstances. [*See*, again, 5 of (43).]

*Exact Commensurability of Periodic Times.—Explanation of this.*

(67) M. Laplace, in the course of his comments on his own hypothesis, especially notices and accounts for "the rigorous equality observed between the angular motions of rotation and revolution of every satellite;" all which will be considered in another connexion.

But, he adds, that "the first three satellites of *Jupiter* present a still more extraordinary phenomenon;" which consists in this, that "the mean longitude of the first minus three times that of the second, plus twice that of the third, is always equal to two right angles."

Next, with respect to the *existing* satellites of *Saturn*, we have the statement of Sir J. Herschel that "A remarkable relation subsists between the periodic times of the two interior satellites and those of the two next in order of distance, viz., that the period of the third (*Tethys*) is double that of the first (*Mimas*), and that

of the fourth (Dione) double that of the second (Enceladus). The coincidence is exact in either case to about the 800th part of the larger period.”<sup>1</sup>

Again, in the *American Journal of Science and Arts, 3d Series*, vol. iii, p. 67 (1872), is an extract from a letter of Prof. Benjamin Peirce to Prof. Newton, in which Prof. Peirce says: “I have discovered three fixed equations between the mean motions of the four outer planets. If the mean motions of Jupiter, Saturn, Uranus, and Neptune are respectively represented by  $n^v$ ,  $n^{vi}$ ,  $n^{vii}$ , and  $n^{viii}$ , these equations are—

$$\begin{aligned} 4n^{vi} + 9n^{viii} &= 16n^{vii} \\ 2n^v + 17n^{vii} + 6n^{viii} &= 12n^{vi} \\ 3n^{vii} + 8n^{viii} &= n^v \end{aligned}$$

. . . . . To which he adds . . . . . “If all the three equations are admitted, the mean motions of three of these planets can be computed when the fourth is given;” and he exhibits the requisite equations. He states, moreover, that the reception of these “involves a laborious revision of the theory of these planets, . . . . . and must seriously change the elements of their orbits.”

Lastly;—to this, Prof. Daniel Kirkwood adds:<sup>2</sup> “The recent note of Prof. Peirce announcing his discovery of some interesting relations between the mean motions of the four outer planets, has recalled my attention to a number of similar coincidences detected by myself several years since, while engaged in a somewhat laborious examination of the planetary elements. Of these the following may be worth putting on record for future discussion:—

$$\begin{aligned} 2n^v - 3n^{vi} - 11n^{viii} &= 0 \dots\dots (1). \\ 2n^{vi} - 21n^{vii} + 30n^{viii} &= 0 \dots\dots (2). \\ 3n^v - 8n^{vi} - 2n^{vii} + 7n^{viii} &= 0 \dots\dots (3). \end{aligned}$$

“The re-examination of the last of these has recently led to the discovery of two others, viz:—

$$\begin{aligned} 68n^{vi} - 325n^{vii} + 257n^{viii} &= 0 \dots\dots (4). \\ 257n^v - 844n^{vi} + 587n^{vii} &= 0 \dots\dots (5).” \end{aligned}$$

. . . . . “The fifth, however, is not an independent equation, but is derived from the third and fourth. . . . It is obvious, moreover, from the same equations, that *no three of the four outer planets can ever be in conjunction at the same time.*”

The more thorough revision indicated by Prof. Peirce would be requisite before all these relations could be definitely settled; but they furnish additional occasion both in the planetary system and in that of Saturn for the explanation which M. Laplace himself has given, in Note VII to the *Système du Monde*, of the special relation apparent in the first of the instances here quoted, viz., that of Jupiter’s satellites.

That illustrious astronomer indicates that “in order to produce the equation with regard to those satellites, already quoted, it would be sufficient that, at first,

<sup>1</sup> *Outlines of Astronomy* (11th edition), (550).  
<sup>2</sup> At p. 208 of the same volume.

there should have been a very close approximation to the conformity in question, and then the mutual attraction of the satellites would rigorously establish such a conformity;" and hence, moreover, "make the mean longitude of the first satellite *minus* three times that of the second, *plus* twice that of the third, always equal to a semi-circumference."

At the same time, as he says, this would originate a periodical inequality dependant on the small quantity by which the mean motions "primitively deviated from the relation which we have announced. Notwithstanding all the care which Delambre took to make out this inequality by observation, he could not discover it; which proves its extreme minuteness, and consequently indicates with very great probability a cause which made it disappear."

M. Laplace then proceeds to show that, on his own hypothesis, the satellites of Jupiter, immediately after their formation, did not move in a perfect vacuum; but that the less condensable molecules of the primitive atmospheres of the sun and of the planet *furnished a resisting medium*,<sup>1</sup> the effect of which would be different on every one of the satellites in question, and when their motions attained the conditions requisite to the establishment of the conformity of motions, the same resistance diminished the inequality to which this relation gave rise, and finally rendered it insensible.

All this may well be extended to the case of *the conformity of periodic-times in Saturn's system*, as well as *those of the periodic-times of the outer planets* already specified.

M. Laplace illustrates the process in question by the retarded motion of a pendulum in a resisting medium; entire revolutions being reduced to oscillations diminished continually by the resistance of the medium, and in the end annihilated; the pendulum coming to rest, and ever after remaining so.

The original passage in which this illustration occurs, is the closing one of the *Système du Monde*; and is as follows:—

"On ne peut mieux comparer ces effets, qu'au mouvement d'un pendule animé d'une grande vitesse, dans un milieu très peu résistant. Il décrira d'abord un grand nombre de circonférences; mais à la longue, son mouvement de circulation toujours décroissant se changera dans un mouvement d'oscillation, qui diminuant lui-même de plus en plus, par la résistance du milieu, finira par s'anéantir; alors le pendule arrivé à l'état du repos, y restera sans cesse."

The changes indicated in the quotation in the next article, contemplate a veritable oscillation, in some measure like this.

#### *Special Characteristics of the Moon, and other Satellites.*

(68) M. Laplace, commenting on his own hypothesis, in the connexion already referred to, (67), thus expresses himself: "One of the most singular phenomena of the solar system is the rigorous equality observed between the angular motions of rotation and revolution of every satellite. We may wager infinity to one that

<sup>1</sup> The italics are our own.

this is not due to chance. The theory of gravitation causes the infinity of this unlikelihood to disappear, by showing us that, for the existence of the phenomenon, it would be sufficient that the motions should have been very little different at their origin.<sup>1</sup> Then the attraction of the planet established between them a perfect equality; but at the same time gave rise to a periodic oscillation of the axis of the satellite directed toward the planet, the extent of it dependant on the primitive difference of the two motions. The observations of Mayer on the libration of the moon and those which MM. Bouvard and Nicollet made with reference to this matter, at my request, have failed to make known this oscillation. The difference on which it depends must, therefore, have been very small; which indicates, with extreme probability, a special cause which first kept this difference within the very narrow limits within which the attraction of the planet could establish an equality between the mean motions of rotation and revolution, and which afterwards destroyed the oscillation which this equality had originated. Both these effects result from our hypothesis. For it will be understood that the moon in the state of vapors, formed, because of the powerful attraction of the earth, an elongated spheroid the major axis of which must be incessantly directed towards that planet, from the facility with which vapors yield to the smallest force which animates them. The terrestrial attraction continuing to act in the same manner when the moon was in a fluid state, at length, in approximating incessantly the two motions of this satellite, caused them to fall within limits such that their rigorous equality began to be established. Afterwards this attraction must, little by little, have annihilated the oscillation which this equality produced in the axis of the spheroid directed towards the earth."

"It is thus that the fluids which covered this planet<sup>2</sup> have destroyed, by their friction and their resistance, the primitive oscillations of its axis of rotation, which now is subjected but to the nutation resulting from the actions of the sun and the moon. It will be readily seen that the equality of motions of rotation and revolution would present an obstacle to the formation of rings and of secondary satellites from the atmospheres of those bodies. Accordingly, observation has thus far indicated none such."

(69) It is claimed that the other satellites of the planetary system resemble the moon in the coincidence of their times of rotation and revolution; and thus presenting always nearly the same side of any satellite toward its primary. This is inferred from special vicissitudes of the light of the satellites *recurring* when they have again arrived *at the same positions* in their orbits around their respective primaries.

Nor is that all. Among the remarkable phenomena presented by satellites is that of their seeming loss of light; all Jupiter's satellites, having, at times, been seen to transit the disk of the planet, in whole or in part, as *dark* instead of *bright* spots; and that sometimes after having *first* appeared *bright* and then *dusky*.

<sup>1</sup> In this connexion, see, again, Note on p. 22.

<sup>2</sup> The Earth.

This—as has elsewhere been indicated by the author of this paper—would seem to be due to the absorption, and, possibly also, to the interference of light on a scale such as Astronomy alone exhibits; of the light, viz., reflected from Jupiter and meeting that of the satellite.

(a) Aside from all that, however, the phenomenon, or rather phenomena, in question would seem to be consistent with the conclusion of a coincidence in the times of rotation and revolution; for the appearance of the satellite, in the course of its transit, as a black spot has, within moderate intervals of succession, recurred when the satellite had returned to a like position in its orbit around its primary.<sup>1</sup>

(b) Admitting the absorption already indicated; then, instructed by the revelations of the spectroscope, we may regard it as probable that the satellite must be *colder* than its primary.<sup>2</sup>

(c) This last would happen—indeed we would have a reason for it—if the satellite, like the moon, had *little or no atmosphere*.

(d) All these analogies would be quite consistent with the hypothesis that all these satellites (including the moon) had been similarly condensed from the nebulous state, and then subjected to the stringent conditions which prevail in satellite systems. The loss of atmosphere is one of the supposable consequences of those stringent conditions; as indeed M. Laplace has intimated, when after stating the distance at which the attractive force of the earth is in equilibrium with that of the moon, he adds: “If at this distance, the primitive atmosphere of the moon had not been deprived of all elasticity, it would be carried to the earth, which could thus draw it to itself, (*aspïrer*). This is, perhaps, the reason why the moon’s atmosphere is so nearly insensible.”<sup>3</sup>

#### *Of the Zodiacal Light.*

(70) As to the region of the zodiacal light; M. Laplace, in speaking of the atmosphere of the sun, says: “The atmosphere at the equator cannot extend beyond the point where the centrifugal force exactly balances gravitation; for it is manifest that beyond that limit the fluid must itself be dissipated. As respects the sun, this point is at the distance from his centre of the radius of the orbit of a planet which would complete its revolution in a time equal to that of the rotation of the sun. The atmosphere of the sun, therefore, does not extend even to the

<sup>1</sup> But the conclusion is not a necessary one. M. Secchi makes the time of rotation shorter than that.

<sup>2</sup> Some recent observations of Jupiter seem to indicate that the planet itself is highly heated—possibly even to the extent of being locally self-luminous. The color of the belts and its variations together seem consistent with all this. [Witness the exquisitely beautiful chromo-lithographs accompanying the Earl of Rosse’s paper in No. 5. of vol. XXXIV, of the *Proceedings of the Royal Astronomical Society*; and Mr. John Browning’s very beautiful representations of similar phenomena in No. 9 of the same volume. Also M. Tacchini’s very remarkable diagram of Jupiter’s appearance; with his explanations (*Comptes Rendus*, tome LXXVI, p. 423).]

<sup>3</sup> Conclusion of Chap. X, of Book IV, of the *Système du Monde*. For a discussion and an explanation of the various phenomena here in question, see two communications, by the author of this paper, to the *Astronomische Nachrichten*, Nos. 1986 and 2012.

orbit of Mercury, and, consequently, it does not produce the zodiacal light, which seems to extend even beyond the earth's orbit. Moreover this atmosphere, whose polar axis must be at least two-thirds of that of the equator, is very far from having the lenticular form which observations give to the zodiacal light."<sup>1</sup>

(71) Next as to the origin and the constitution of the material which gives us the zodiacal light, we have: "If, among the zones abandoned by the atmosphere of the sun, there should be molecules too volatile either to combine themselves, or to unite with the planets, they ought, while continuing to circulate about the sun, to present all the phenomena of the zodiacal light without opposing a sensible resistance to the diverse bodies of the planetary system, either because of the extreme rarity of those volatile molecules, or because their motion is very nearly the same with that of the planets which they encounter."<sup>2</sup>

It will be observed that the first of the two quotations, here made, intimates it as probable that the material from which the Zodiacal Light proceeds, itself extends beyond the earth's orbit. This is, in fact, intimated by the existence of what in German accounts of observations of the Zodiacal Light has been designated as the *gegenschein*; which is seen in the part of the heavens opposite to the sun; the existence of which phenomenon is established by numerous observations, such especially as are detailed in various numbers of the *Astronomische Nachrichten*.

(72) Both eastern and western appearances occurring simultaneously are reported by the late Rev. George Jones, A.M., chaplain in the U. S. Navy; these phenomena being, among numerous others, the description of which, and other things connected with them, itself occupies the whole of vol. iii. of the *Report of the U. S. Japan Expedition*; and the extent of the light to *both sides of the heavens* is confirmed by the observations of Col. Charles G. Forshey, U. S. A., made while he was stationed in an elevated and dry region of Texas; where, as stated by Col. Forshey to the author of this paper, that phase of the phenomenon was a common occurrence; though the appearance of the Zodiacal Light in lower Louisiana, as described by him, was very different.<sup>3</sup>

(73) All this makes it more difficult to admit that the material in question can be maintained in position, with the sun for its centre of reference; the conservative

<sup>1</sup> *Système du Monde*, Book IV, Chap. X.

<sup>2</sup> *Système du Monde*, Note VII.

<sup>3</sup> In Col. Forshey's manuscript notes, which he has since confided to me, the Zodiacal Light is described as being "very distinct across the heavens," Nov. 10, 1858, at 10 o'clock P. M. As delineated on star charts, the outlines on this occasion, as on many others, approach to a hyperbolic form, the central line of the luminous band being in the position of an asymptote to the two edges; or—if the comparison may be allowed—the appearance often was that of an enormous trumpet, the lower end widening rapidly and extensively; and on the occasion here referred to, *two* such appearances are delineated, as having been observed; the broad ends spreading out to the horizon, on opposite sides, and the narrow portions united midway.

On the 9th of May, 1860, the phenomenon is described as being "faintly visible across the canopy;" though the whole display is characterized as being "rather faint;" while the "evening" is noted as being "splendidly clear."

Also Nov. 13, 1859—"Not a very bright display. Still column very distinct all the way across the sky."

And, in a "Note" under the date of March 31, 1858, Col. Forshey expressly says: "I now begin to think that well-trained eyes can see it all the way round, at all times that are clear and moonless."

influence of the great planets being not supposable within the extended limits of the solar system; though the satellites of Saturn, [*Note* 3 to 7 of (43)], are efficient in that way, maintaining the position of the rings, under the more stringent conditions of a closer arrangement.

Added to this, is the consideration of the enormous extent which would seem to be required on both sides of the ecliptic, to account for the great breadth of the *base* of the zodiacal illumination, even after the disappearance of twilight in the evening, or before daylight in the morning; all which seems to be true of *the more dense*, and, if surrounding the sun, also *the more distant portion* of the material in question, which ought, unless uncommonly extensive, to be seen *under a smaller angle* than the other portions of the same; a difficulty to which the hypothesis recently advanced by Mr. Richard A. Proctor, F.R.A.S., viz. that the Zodiacal Light is due to a closely arranged group of meteors, would seem to be especially liable; and all the more so, if "assuming" (as he himself says we are bound to do) "a considerable degree of flatness in the actual figure of the zodiacal disk, and more especially of its more distant portions."<sup>1</sup>

And just *that* difficulty still remains if we were even to *admit* Prof. Arthur W. Wright's conclusion from his recent experiments on the *polarization* of the Zodiacal Light, as far as this—that "the light is reflected from matter in a *solid state*;" since, he adds, in explanation of the same that this solid matter is that of "innumerable small bodies revolving about the sun in orbits of which more lie in the neighborhood of the plane of the ecliptic than near any other plane passing through the sun."<sup>2</sup>

Now this portion of the hypothesis of Prof. Wright, Mr. Proctor, and, it may be, others—whatever may be the special composition of the material in question—would seem to require that the apparent form of the Zodiacal Light should be somewhat like that of the head of a comet, with the *expansion* beyond it extending *upward* from the sun; whereas the actual appearance and position are both the reverse of that; the *broad* base near the horizon, and the *narrow* and curved termination at *the upper end*.

And then, moreover, it would seem, on the part of the hypothesis here considered, that, in any event, there must be a conspicuous central beam or core of the Zodiacal Light; which we do not find.

And, lastly, what shall be said of the *planetary perturbations*, which, it would seem, ought to be superinduced by such a closely arranged group of meteors; especially if the "light" be indeed "reflected from matter in a *solid state*?"

Other objections to hypotheses which would make the material to which we owe the Zodiacal Light to be an appendage of a lenticular or other form, referable to the sun as its centre, are very exhaustively considered by Chaplain Jones in the volume already referred to. The hypothesis that the Zodiacal Light is due to

<sup>1</sup> In a long and carefully considered *Note on the Zodiacal Light* in the *Monthly Notices of the Royal Astronomical Society*, vol. xxxi, No. 1 (Nov. 11, 1870).

<sup>2</sup> *American Journal of Science and Arts, Third Series*, vol. vii. p. 457 (No. 41—May, 1874). Will, after all, our terrestrial experience as to the conditions of *polarization*, justify us in making *it* a *criterion* of the *state* of anything so peculiar as the matter in question?

reflection from the earth's atmosphere is also discussed and rejected by him. Upon this, however, it will not be necessary here to comment; as it, most probably, is no longer insisted upon by any one.

(74) It remains, then, to consider *with what modifications* we may admit Mr. Jones's hypothesis; that the nebulous material which gives the Zodiacal Light is a terrestrial appendage; and also what is the conservative force, which may insure its preservation of form, and its maintenance in its revolution around the earth, even in close proximity to the moon.

Antecedent to all that, however, will be found to be the questions of density and of mode of illumination, as well as, in its proper connexion, the question of parallax.

The density of the material in question seems indeed to be that intimated in the description of M. Laplace already quoted, (71); viz. that which pertains to the state of molecules "too volatile either to combine themselves, or to unite with the planets." And this is confirmed by the spectrum-analysis; the result of which has led to no other reliable conclusion than that of the extreme rarity of this same material.<sup>1</sup>

This same rarity of the material in question is withal indicated by its transparency.

Of this Rev. George Jones says, under date of Dec. 30, 1854 (in lat. 10°46' N., long. 89°31' W. of Greenwich): "I also, this morning, gave attention to the stars as seen through the Zodiacal Light, and found, even to 4<sup>h</sup> 30<sup>m</sup>, when the effulgent light below the zigzag lines (in the chart) is very strong, that with the naked eye I could readily make out stars of the 6th magnitude within the effulgent light; . . . . also a line of four stars below 19 Libræ, and ranging with  $\beta$  Libræ; . . . . the two northernmost of these last are of the 7th magnitude, yet I think the naked eye detected them, even within this effulgent light; but the last are near its upper edge. All this shows the great transparency of the substance giving the Zodiacal Light."<sup>2</sup>

(75) The consideration of these phenomena leads to the conclusion, That this light proceeds from particles which, as respects size, are, at most, all but *molecular*, and if discrete, and, possibly, "solid," yet *excessively* small solids. It then must also largely be *transmitted* light; and so the illuminated material *appear brighter in the special direction in which the light is transmitted*. Chaplain Jones illustrates this in part, when he says that "it seems to be quite conclusive, on an inspection of these charts, that *we never at any one time see the whole actual extent of the Zodiacal Light*. This subject can, perhaps, be elucidated by noticing a common event—a cloud silvered at one edge by the rays of the declining sun. The sun may be shining on the bordering, quite around that cloud; and, if so, it is sending off from every portion of the border, an equally brilliant silvery light. But our eye is in a position to

<sup>1</sup> Such is in effect the statement of Prof. Charles A. Young (as the result of his experience and that of others), made in a personal communication with the author of this paper.

<sup>2</sup> Report of Japan Expedition, vol. iii, No. 271, at p. 542.

catch this reflection from only one portion of it; and the rest is dull to our vision. If we could with great rapidity change our positions, other portions of the silvered edge would show themselves according to our changes of place. So also, when a rainbow is presented to our eye; the myriads of drops of falling water in the whole rain-shower are sending off from each drop reflections of light in all directions, and the universal atmosphere about us is full of these brilliant variously-colored rays; but only that portion, which, to us, forms the rainbow arch, can reach our eye; and all the rest is lost to our sight."

"So it is also with the Zodiacal Light; and the proof that we never see the whole of its extent at once, is manifest in the following facts:—

"1. When I was in a position *north* of the ecliptic, the main body of the Zodiacal Light was on the *northern* side of that line.

"2. When I was *south* of the ecliptic, the main body of the Zodiacal Light was on its *southern* side.

"3. When my position was *near* or *on* the ecliptic, this Light was equally divided by the ecliptic, or nearly so.

"4. When, by the earth's rotation on its axis, I was, during the night, carried rapidly to or from the ecliptic, the change of the apex, and of the direction of the boundary lines, was equally great, and corresponded to my change of place.

"5. That, as the ecliptic changed its position as respects the horizon, the entire shape of the Zodiacal Light became changed, which would result from new portions of the nebulous matter coming into position for giving us visible reflection; while portions lately visible were no longer giving us such reflection."<sup>1</sup>

(76) The phenomena here commented upon all serve to confirm the assertion, (75), that the zodiacal illumination must largely be transmitted light; and so the illuminated material *appear brighter in the special direction in which the light is transmitted*; as the sun illuminates the partially transparent vapor in our atmosphere through rifts in the clouds, and thus produces the appearance familiarly described as "the sun drawing water."<sup>2</sup>

(77) The light being transmitted, other phenomena would also be in place, among which are *absorption*—possibly *interference*—and also *fluorescence*; new waves being originated in this case, as well as, perhaps, in that of the comets; the spectrum-analysis of whose light seems to show, among other phenomena, characteristics of self-luminous material.

(78) To this it may now be added, that the nebulous ring of Chaplain Jones, may well be regarded as having, indeed, not the *lenticular form* attributed to the

<sup>1</sup> "The first four of these results were not always uniform; but the exceptions were few, and were probably occasioned by the nebulous ring's not lying exactly in the plane of the ecliptic." From the *Introduction* to Chaplain Jones's Report, pp. XVI and XVII.

<sup>2</sup> Mr. Proctor also seems inclined to admit the possibility of a more intense illumination in special directions; though not decided as to its cause, when he says at the close of his Note on the Zodiacal Light, referred to in (73): "If some solar action, for example, rouses luminosity in certain definite directions—as, for instance, near the plane of the Sun's equator—in some such way as light is caused to appear along radial lines through and beyond the heads of comets, our power of theorizing from such considerations as have been dealt with in this paper would be limited."

material giving the zodiacal light by older hypotheses (which he does not claim); nor yet that of a ring like those of Saturn; nor yet a ring of greater thickness, partially luminous indeed in appearance, as Mr. Jones would have it; but we must have for it the form of what may rather be termed a *girdle*, of *no great thickness*, it may be—it is too translucent for that—but yet of very considerable width, such as will provide for the broad base of the Zodiacal Light, and the extended elliptical spot which exhibits the “*gegensein*”<sup>1</sup> opposite to the sun; and which latter would seem to be almost wholly due to reflection. There may also be some reason to suppose that the curvature of the girdle, on the one side at least (that on which the “*gegensein*” appears) is such as would be due to a spheroidal shell such as has been described in *Article* (37) of this paper. Such a girdle, withal, could not always—perhaps ever—have all its breadth enveloped in the *earth’s shadow*.

*How the Girdle is maintained.*

(79) The question at once becomes a pertinent one, How can such a girdle escape destruction by the continued perturbation of the moon, acting in close proximity?

The answer to this question may be found, if the girdle be so situated that ITS TIME OF REVOLUTION AROUND THE EARTH SHALL BE EQUAL TO, AND IN THE SAME DIRECTION WITH, THAT OF THE MOON. The conditions requisite to fulfil this will first be considered, and then the phenomena that seem to be accordant with the actual maintenance of such conditions.

(80) If the *earth’s* attraction *alone* were concerned, the form of the revolving girdle must, it would seem, be that of a spheroidal shell; such as that indicated in (37). The attraction of the moon will distort this, yet so that the shape shall also be consistent with the stringent condition as to the periodic time.

Fig. 13.

Fig. 14.

<sup>1</sup> *Counter-gleam*, we might perhaps term it; though that scarcely seems so apt as the German word for the same thing, here quoted.

The middle line of the girdle will, notwithstanding, form an oval, which, at any time, in its arrangement around the earth, will not anywhere be found at a distance differing much from that of the moon at that time; except in those portions comparatively near to the moon.

That part of the oval nearest the moon may pass between the moon and the earth, as in *Fig. 13*; or else outside of the moon, as in *Fig. 14*; in both of which *E* marks the position of the earth, and *M* that of the moon.

In the determination of the dimensions in either case, it will be convenient to ascertain the periodic time of a particle, or of an inappreciable mass, revolving around the earth at the mean distance of the moon; which we may obtain by the aid of the following formula, in which (*T*) will be put for the periodic time; *M* and *m* representing the masses in question, and *r* the radius-vector; and we have

$$(T) = \frac{2\pi r^{\frac{3}{2}}}{\sqrt{M+m}} \dots \dots (1).^1$$

Then, when *m* is insensible,

$$(T') = \frac{2\pi r^{\frac{3}{2}}}{\sqrt{M}} \dots \dots (2);$$

and, when *r* is the same for both, from these we also have,

$$\frac{(T')}{(T)} = \sqrt{\frac{M+m}{M}} \dots \dots (3); \text{ or}$$

$$(T) = \frac{\sqrt{M+m}}{\sqrt{M}} (T') \dots \dots (4);$$

which, otherwise expressed, is

$$(T') = \sqrt{\frac{M+m}{M}} \cdot (T) \dots \dots (5).$$

Then, *1st*—Making special application of either *Eq. (4)*, or *Eq. (5)* to the example in which *M* and *m*, respectively, represent the masses of the earth and the moon, and (*T*) the moon's periodic time, we shall have the periodic time of a particle, or of an insensible mass, revolving around the earth at the distance of the moon.

*2d.* Ascertain the periodic time (*t*) of the same insensible mass, revolving about the earth, at the assumed distance *EA*, by the application of *Kepler's 3d Law*.

*3d.* The attractive forces of the moon and the earth, respectively, acting at *A* may be separately computed in accordance with the law of gravitation ( $\frac{M}{d^2}$ ), and then taking the *difference of* the two forces, when the state of things is that represented in *Fig. 13*; and expressing this difference in terms of the earth's force *F*, viz. as  $\frac{p}{q}F$ ; then (with (*t*), the periodic time around the earth of an insensible mass revolving at distance *EA*, *already computed*), we shall have

<sup>1</sup> Encyclopædia Metropolitana—*Physical Astronomy*, Section V.

$$\frac{(\ell')^2, \text{ for } \frac{p}{q}F}{(\ell)^2, \text{ for } F} = \frac{F \text{ itself}}{\frac{p}{q}F}; \text{ whence}$$

$$(\ell')^2 = \frac{F}{\frac{p}{q}F} \cdot (\ell)^2; \text{ and}$$

$$(\ell') = \left\{ \frac{F}{\frac{p}{q}F} \cdot (\ell)^2 \right\}^{\frac{1}{2}}$$

Then if  $(\ell')$ , thus computed, be found to be equal to the moon's own periodic time, the point  $A$  will have been accurately ascertained; the particle, or the insensible mass (in the line  $EM$ ), completing its revolution at the distance  $EA$ , in the same time with the actual revolution of the moon around the common centre of gravity of the moon and the earth.

But if  $(\ell')$  differ at all from *that*, the difference may be exhausted by the continued application of the method of trial and error.

When  $A$  is situated beyond the moon (in accordance with the representation in *Fig. 14*) the *sum* of the attractive forces of the two bodies must be made to enter into the equation to determine the value of  $(\ell')$ , instead of the difference of those same forces. So also, for the distance from  $E$  to  $B$ , on the opposite side of the earth.

(81) Now the division or the extension of  $EM$  (as the case may be) so as to give the distance  $EA$ , this depends upon the forces in question, and, ultimately, on the ratio of the masses, and not upon the absolute length of  $EM$ . Hence  $EA$  and  $EB$  will each have a constant ratio to  $EM$ ; whether the moon be in apogee, or in perigee, or at the mean or any other distance. The same is true of the distance of the moon from the common centre of gravity of the moon and the earth, *i. e.* of the *radius-vector of the moon's orbit*; and for the same reason.

Now,—(a.) Every other of the quantities in question having, after this manner, a constant ratio to  $EM$ ; it will follow that, under all their variations of value, the value of any one of the quantities will preserve a constant ratio to the coexistent value of any other; and therefore, specifically, to the coexistent value of the *moon's radius-vector*; or the square of the one, a constant ratio to the square of the other.

(b.) Next, as  $M$ ,  $E$ ,  $A$ , and  $B$ , under the conditions in question, are preserved in the same straight line; it follows from the doctrine of parallels, that the *angular change of direction* of  $M$  revolving about the common centre of gravity of  $M$  and  $E$ , or that of  $A$  and  $B$  revolving about  $E$ , will be *the same* with reference to any fixed direction in space, such as that of  $EM$  (at any instant), or with reference to its parallel; or the same will be true with respect to the first tendency to such change, *i. e.* its *differential*.

(c.) Hence also, especially, the angular change of direction which would take place, were such a tendency preserved during the next *unit of time*, *i. e.* the co-

existing angular velocity of  $M, A, B$ , (in their revolution of every one of them around its centre of reference) would, in every instance, have the same value.

(*d.*) But this *same* angular velocity in the moon's orbit varies inversely as the square of the *radius-vector*, and the coexisting values of the squares of  $EA$  and  $EB$ , respectively, having (as already shown) constant ratios to *that*; their ratios may be substituted for the ratios of the respective coexisting values of the squares of the radii-vectores themselves; and the inversion of the one for the inversion of the other.

(*e.*) By substitution, then, the respective squares of  $EA$  and  $EB$  are inversely as the coexisting angular velocities in the moon's orbit.

(*f.*) But the same angular velocity being (as also shown) common to all the three masses in question; every one of those masses will also have its angular velocity inversely as the square of its own radius-vector; and that will imply the principle of *the conservation of areas*; and thus maintain not only for the moon, but also for the other masses, in the consentaneous revolution of all, a *dynamical equilibrium*.

(*g.*) Then withal the constancy of the ratios already specified, will secure, under the coexisting similar change of angle, the same ratios among the radii-vectores of all the three trajectories here in question; and just all that implies that the *same polar equation* will apply to all the three.

(*h.*) Hence the trajectories of  $A$  and  $B$  are both *ellipses*; as well as (perturbations apart) is the orbit of the moon; even more than this, under those stringent conditions (common to all); viz. the trajectories are all *similar ellipses*.

(82) The positions of the points  $A$  and  $B$ , on the supposition that the girdle on the one side, is between the earth and the moon, as in *Fig. 13*, is exhibited in the following table; the distances represented being in terms of the earth's equatorial radius.

|                                           | IN PERIGEE. | AT MEAN DISTANCE. | IN APOGEE. |
|-------------------------------------------|-------------|-------------------|------------|
| MOON'S DISTANCE.....                      | 56.964      | 60.273            | 63.583½    |
| ( $EA$ ) Internal Distance of Girdle..... | 48.309      | 51.116            | 53.922½    |
| ( $EB$ ) External Distance of Girdle..... | 56.790      | 60.090            | 63.389     |

On the supposition that the girdle encompasses the moon, as in *Fig. 14*, we have:—

|                                           | IN PERIGEE. | AT MEAN DISTANCE. | IN APOGEE. |
|-------------------------------------------|-------------|-------------------|------------|
| MOON'S DISTANCE.....                      | 56.964      | 60.273            | 63.583½    |
| ( $EA$ ) External Distance of Girdle..... | 66.426      | 70.285            | 74.144½    |

(83) As  $A, B$ , and the moon thus describe similar ellipses with their radii-vectores coincident in the same straight line; it is manifest that the portions of the girdle in the immediate neighborhood of  $A$  and  $B$  will *expand* (the material

being readily adjustable) as the moon passes from perigee to apogee; and they will contract as the moon passes from apogee to perigee; the cohesive power and the gravitation of outer to inner portions being, in any event, insensible; and so each particle or molecule moving in its independent, or nearly independent, ellipse very much as Sir J. Herschel has intimated that the molecules of comets might move.<sup>1</sup>

Then, too, a *permanent* tide must influence and control the form of the girdle; this tide (with the arrangement as in *Fig. 14*) being in some sense *supra*-lunar, instead of *sub*-lunar, in the region of the crest of the girdle extending beyond the moon.

By such a tidal action an *accumulation of material* will be determined toward the *two extremities* of that axis of the girdle, which at any time passes through the two centres—that of the earth and that of the moon—and which is extended to the girdle on both sides [*i. e.* toward *A* and *B* in either of the cases represented, the one in *Fig. 13*, and the other in *Fig. 14*].

And the portions of the adjustable material here specified having themselves been once so adjusted (radii-vectores and all) as to be held, or very nearly held, in a dynamical equilibrium, such as is specified in (81); the compulsory power of the forces acting on such material, under such stringent circumstances, might well be supposed to bring about the form required to secure a dynamical equilibrium of the girdle; though the oscillations, in various directions, antecedent to that, would present a problem of no ordinary difficulty.

However all that may be—the dynamical equilibrium of all parts of the girdle being once established, the state of things afterward would be eminently conservative of the same; such being especially the case with respect to *the various* actions, which, under other conditions, might be eminently destructive.

(84) If the girdle (as at *A* in *Fig. 13*) were between the moon and the earth, *its* curvature would be *diminished* in the direction perpendicular to the moon's orbit, by the moon's own action; though the curvature would be *increased* by the action of the moon, on the opposite side; as was, indeed, intimated, though not at all explained, in (78). But if the girdle (as at *A* in *Fig. 14*) were outside of the moon, the curvature (perpendicular to the moon's orbit) would be greater still.

(85) The second thing proposed in this connexion, was to consider the phenomena which seem to be accordant with the state of things thus far represented as being merely supposable. With respect to these phenomena, it may be observed, that the hypothesis of the girdle having the same periodic time with the moon suggested itself as a necessity, to insure the preservation of the girdle itself; and, in the brief interval which has since elapsed, the variations of the Zodiacal Light have, to some extent, been carefully noted, and *then* referred for explanation to the hypothesis.

And here the phenomena seem to be more consistent with the arrangement of the girdle as represented in *Fig. 14*; the point *A* being situated *beyond* the moon.

---

<sup>1</sup> Cabinet Cyclopædia—*Astronomy* (488).—With this Prof. Wright's conclusions, (73), with respect to the *constitution* of the material in question would not be inconsistent. See, again, *Article* (73).

With that in view, the special appearances of the Zodiacal Light may be arranged as follows:—

*Case 1st.* The Zodiacal Light appears narrow and towering high just about the time of the new moon; as though the sun's light were indeed transmitted, at that time, through the least curved, and, probably, somewhat rarer sides of the oval-shaped girdle; and that through a great part of the length of the oval. (Fig. 15.)

Fig. 15

*Case 2d.* After the new moon, when the moon is approaching her first quarter; when the moon has set, and the twilight has disappeared, the Zodiacal Light does not extend so high as in the preceding case, and its termination is broader, and not so sharply curved, and the intensity of the light, withal, is not especially conspicuous (as in Fig. 16, for Zodiacal Light of the morning), as though the sun's light indeed, in all its transmission, passed through the rather less dense portion of the girdle; and passed out of it in a direction more across the girdle and not so nearly at a tangent to it (in its exit under these circumstances), as in the preceding case.

Fig. 16.

*Case 3d.* After the full moon, and when the moon is approaching her last quarter; then, before the rising of the moon, and after the end of twilight, a luminous spot of considerable size, and, in appearance, like the brighter portion of an aurora borealis, occupies the place in the Zodiacal Light which is quite accurately opposite to the moon's place; and night after night, as the moon advances, this luminous spot rises among the stars, so as still to keep opposite to the moon; as though the somewhat more dense

Fig. 17.

portion at the further end of the oval (as respects the moon) were thus more conspicuous than the other portions then in view; and then the upper extremity of the Zodiacal Light is broader and not so sharply pointed as in Case 1st; as though for the reason assigned in Case 2d. (Fig. 17.)

*Case 4th.* After the last quarter and before the new moon, the Zodiacal Light of the evening is again faint, as it was before the first quarter; as though the illumination were wholly of that part of the girdle beyond the region near the longer axis. (Fig. 18.)

*Case 5th.* When the moon is nearly in quadrature, it would seem that the Zodiacal Light must appear short and bright, if apparent at all after the twilight of the evening, or before the twilight of the morning. For the sun's light would be transmitted by a short course through the most curved portion, near to one end of the longer axis of the oval. (Fig. 19.)

(86) Increase of brightness might be looked for, with the moon in perigee; and of extent, with the moon in apogee. Traces of something like one and the other have been apparent.

(87) After an examination of Chaplain Jones' very numerous charts, a selection was made of those which seemed to exhibit instances in which the light was most

extensive, or most conspicuous, and others in which, in one or both respects, the light seemed to be deficient (the character of the light, and not the position of the moon, furnishing the guide in the selection); and *then* the age of the moon, and her position in her orbit were ascertained, for a comparison of the phenomena with theory.

The following instances were then classified with reference to our hypothesis now under discussion. The *Nos.* are those of Mr. Jones' charts:—

*Examples under Case 1st.*

No. 219.—Morning of Sept. 21, 1854; 1 day before new moon.

No. 220.—Evening of Sept. 23, 1854; 1 day after new moon.

No. 232.—Morning of Oct. 20, 1854; 1 day before new moon.

No. 233.—Morning of Oct. 21, 1854; the day of new moon.

No. 243.—Morning of Nov. 21, 1854; 1 day after new moon.

No. 259.—Morning of Dec. 19, 1854; the day of new moon.

(A very marked instance; and not only was the day that of *new moon*, but the moon was also *in perigee*.)

Mr. Jones, without any reference to the moon's age, or to her distance from the earth, says of the zodiacal light, "At 2h. the eastern zodiacal light was bright, at 3h. 30m. quite so. At 5h. it was as brilliant as I have ever seen it, and was especially so within the zigzag" (waving lines toward the lower part of the diagram), "where the light had more of a cone shape than I ever saw it have before.<sup>1</sup> . . . Sun rose at 6h. 57m."

*Approximation to Case 1st.*

No. 49. Morning of Sept. 2d, 1853; 1 day before new moon.

*Examples under Case 2d.*

No. 31. Evening of July 9th, 1853; 3 days after new moon.

No. 114. Morning of Feb. 1st, 1854; 3½ days before first quarter.

---

<sup>1</sup> The description here is such as might, in anticipation, have been dictated by the hypothesis under discussion.

*Case 2d, or Case 4th.*

No. 161.—Evening of May 29th, 1854; 3 days after new moon.

No. 237.—Morning of October 30th, 1854; 2 days after first quarter.

*Examples under Case 3d.*

No. 212.—Evening of Sept. 12th, 1854;  $1\frac{1}{4}$  day before last quarter.

No. 213.—Evening of Sept. 13th, 1854;  $\frac{1}{2}$  day before last quarter.

*Examples under Case 4th.*

No. 18.—Evening of June 29th, 1853;  $1\frac{1}{2}$  day after last quarter.

No. 60.—Morning of Sept. 30th, 1853;  $2\frac{1}{2}$  days before new moon.

No. 215.—Evening of Sept. 16th, 1854; 2 days after last quarter.

*Examples under Case 5th.*

No. 67.—Morning of Oct. 8th, 1853; 1 day before first quarter.

No. 214.—Evening of Sept. 14th, 1854; day of last quarter.

No. 239.—Evening of Nov. 11th, 1854; 1 day before last quarter.

No. 241.—Evening of Nov. 13th, 1854; 1 day after last quarter.<sup>1</sup>

(88) Mr. Jones also gives examples of “Moon Zodiacal Light.”

(89) Baron Humboldt, commenting on Rev. Mr. George Jones’s observations, quotes from his own ship-journal on his voyage from Callao to Acapulco, and speaks of the brilliancy of the Zodiacal Light as exceeding anything which he had previously witnessed. The time when this was observed was from the 17th to the 19th of March, 1803. Indeed the intensity of the light increased for five or six nights after the 14th. Height  $39^{\circ} 5'$ .<sup>2</sup>

As the moon was new on the 23d, this bright light must have begun before the last quarter; and will present a probable instance of *Case 3d*, passing into and beyond *Case 5th*.

But, strangely enough, Baron Humboldt finds occasion to add: “We did not see the Zodiacal Light the 20th and 21st of March, *although the nights were of greatest beauty.*”

Now something—perhaps not a little—of that may have been due to differences in the state of moisture of the atmosphere, such as those, (72), of which Col. Forshey has informed us. But the time being withal from two to three days before the new moon, the sun’s light would, on the hypothesis here in question, be transmitted through the curved portion of the girdle a little in advance of the longer axis.

The length of the transmitted portion would not be great, and the upper end would set almost as soon as the twilight ended.

(90) In the account of Prof. C. Piazzi Smyth, Astronomer Royal at Edinburgh, of his expedition to Teneriffe, under date of Aug. 19th, 1856, speaking of the Zodi-

<sup>1</sup> See *Astronomische Nachrichten*, No. 989.

<sup>2</sup> The dates with reference to the phases of the moon are but close approximations; yet such as are quite sufficient.

acal Light, he says: "So bright was it toward the base that it produced a weak reflected glow to the west, and we could occasionally fancy a tail of the faintest conceivable light extending nearly to the zenith." (Length of the bright light was  $63^\circ$ .) "Nevertheless there was no doubt of the lenticular form of the chief mass of light, and the place of its apex as measured, was always consistent enough."<sup>1</sup>

This was almost three days after the full moon, and seems to present an example of *Case 3d*. Under the date of Sept. 8th, Prof. Smyth says of the Zodiacal Light—"bright at base, glowing toward the lower part of the axis."<sup>2</sup>

This was one day after the first quarter of the moon; and we here would seem to have an example of *Case 5th*.

(90 *bis*) The observations of Col. Charles G. Forshey, already alluded to in (72), were made while Col. Forshey was superintendent of the Texas Military Institute (Lat.  $30^\circ$  N., Long.  $96^\circ 25'$  W. of Greenwich), in 1858, 1859, and 1860.

Among these observations we find the following, which seem to furnish *consistent* examples under the *Cases* described in (85); and the list might readily be extended.

*Case 1st.*

- Evening of Oct. 5, 1858; 1 day before new moon.
- Evening of Nov. 6, 1858; 1 day after new moon.
- Evening of Nov. 7, 1858; 2 days after new moon.
- Evening of March 3, 1859;  $\frac{1}{2}$  day before new moon:—
- Light narrow, except near the horizon, and towering high.

*Case 2d.*

Evening of Oct. 12, and morning of 13, 1858; between new moon and the first quarter. A midnight band of light seems to be delineated; such as will also be noted among the observations under *Case 5th*.

Approaching to the conditions of *Case 2d*:—

- Evening of March 31, 1858;  $2\frac{1}{2}$  days after full moon.
- Evening of Nov. 10, 1858; 3 days before the first quarter of the moon.
- Evening of Nov. 13, 1859;  $3\frac{1}{2}$  days after full moon.

[The three last-mentioned instances are specially described in *Note 3* to (72).]

Evening of Nov. 11, 1858:—

This observation may be specially classified with the preceding three. It was made three days before the first quarter of the moon. The position, therefore, is nearly that of *Case 5th*.

*Case 3d.*

Evening of April 22, 1859, 2 days before the last quarter of the moon.

Figure seems to show the peculiar bright spot indicated in the description of our *Case 3d*, of this *Article*.

*Case 4th.*

Evening of Oct. 29, 1858; day of last quarter of the moon.  
Time 11*h.* to 12*h.* P. M.

A midnight band with parallel edges. The figure seems to indicate that the band was about  $7^\circ$  or  $8^\circ$  wide. The appearance is such as it might be if the light were reflected at all but right angles to the girdle.

Evening of April 4, and also that of April 5, 1858; two and one days, respectively, before the last quarter of the moon.

In the evening of April 5, the light is expressly noted as being visible "entirely across the heavens, from Aries at least to Libra."

Evening of Oct. 27, 1858; nearly one day before the last quarter of the moon.

The light seems to have, consistently, been short but considerably bright.

Both characteristics are more distinctly manifest, in the evening of Oct. 28, 1858; day of the last quarter of the moon.

Evening of Dec. 28, 1858; about 2 days after the last quarter of the moon.

Light short and rounded at the top, and the base very broad.

Evening of Jan. 15, 1860; 1 day after the last quarter of the moon.

Light described as having been "intensely bright;" and, in the drawing, it tapers rapidly.

(91) Among the *Notes on the Zodiacal Light*, by Rev. Samuel J. Johnson (*Proceedings of Royal Ast. Society for March, 1874*), we find—"What Humboldt speaks of as the 'mild pyramidally-shaped zodiacal light, very visible to the unassisted eye' has been displayed here" (at *Upton Helions Rectory, Crediton*) "this winter with far more distinctness than I have noticed since Feb. 21, 1870, when I witnessed a vivid appearance of the phenomenon from Lytham, on the Lancashire coast. It was conspicuous, amongst other nights, on February 8, when the impression that Tycho mistook the light for the 'abnormal vernal evening twilight,' appeared at first sight almost pardonable."

This seems again to present an example of our *Case 5th*.

"Feb. 16. Sky clear for a brief interval about 8 P. M. The conical figure very fairly defined, except at the apex, where the curvature was somewhat difficult to make out. *Mars*, situated nearly on the axis; about which point the light seemed equal in brightness to that portion of the *Milky Way* that passes through *Cassiopeia*. Near the horizon the intensity was decidedly greater,  $\nu$  *Ceti* appeared just outside the cone of light; the head of *Aries* faintly involved in it; it could be traced, though with difficulty,  $3^\circ$  or  $4^\circ$  above the *Pleades*."

Again, a remarkable example of our *Case 1st*. For this was the day of the *New Moon*, and the moon was  $1\frac{1}{4}$  day from the *Perigee*. Confirmed this is withal by the next observation.

"Feb. 18. Could be readily followed before the moon set. . . . Clear extent at the base  $30^\circ$  to  $35^\circ$ . Not quite so brilliant as on the 16th; I fancied a slight reddish tinge in the brighter portions."

Appropriately descriptive of our *Case 2d*.

"March 6. The Zodiacal Light again conspicuous. In extent and general features unaltered; in intensity scarcely so great. The clearest defined portion lay between  $\nu$  *Ceti* and  $\gamma$  *Arietis*; at lower altitudes the light, although brighter, appeared very much diffused. *Mars* about  $5^\circ$  left of the axis."

An example of our *Case 3d*. "The clearest defined portion" was nearly *opposite* to the moon, then  $3\frac{1}{2}$  days past the full, and  $1\frac{1}{3}$  day beyond the apogee.

"March 7. With regard to the earliest visibility of the light, it was not noticeable till 15m. after stars of the brightness of  $\gamma$  *Arietis* had shone out, and not quite so soon as the *Milky Way* at equal altitudes. Its whiteness more dusky than the latter. At an altitude of about  $20^\circ$ ,  $\eta$  and  $\alpha$  *Piscium* (the latter just within the boundary) were somewhat dimmed by its intensity."

This is followed by another *Note on the Zodiacal Light*, by E. B. Knobel, Esq., who writes from *Stapenhill Burton on Trent*, and says: "I would beg to direct attention to the unusual brilliancy of the Zodiacal Light this winter. . . ." On two clear evenings in the first week in January, on January 17, at 6.45 P. M., and, lastly, on Feb. 8, at 7 P. M., it appeared as an elongated luminous cone, the apex of which, on January 17, extended nearly to the star  $\gamma$  *Arietis*, and on Feb. 8, the apex just enclosed  $\eta$  *Piscium*.

"It appeared nearly as bright as the *Milky Way*, and sufficiently bright to attract the attention of a casual observer.

"I should mention that my situation is quite away from the town, and sufficiently high to be above the mists of the valley."

The observation of Jan. 17 affords another good example of our *Case 1st*; the date being a little more than  $\frac{1}{2}$  a day before *New Moon*, and about 3 days before the moon arrived at the *Perigee*.

The observation of Feb. 8 confirms that of Rev. Samuel J. Johnson of the same date, previously quoted.

These observations are, moreover, all confirmatory of those made about the same time, as well as at other dates, at the College of New Jersey, by the author of this paper; and which, indeed, furnished the data for the distinction of the various *Cases*.

[A very little observation will suffice to make it very evident, that under circumstances in other respects entirely similar, the fact of the atmosphere being *dry* will notably affect the apparent extent as well as brightness of the Zodiacal Light; in accordance with the special, and even uniform, experience of Col. Forshey, already referred to in (72) and *Note*.]

(92) Chaplain Jones also speaks of pulsations in the Zodiacal Light; as having been observed by himself and others. His synopsis of these observations at p. XIII of his Introduction is: "Some time early in 1854 I saw in a newspaper a brief notice of the pulsations of the Zodiacal Light seen at Kew Observatory; but as the newspaper did not state where they were observed, or the authority, and as I had now been observing for a year without having noticed anything of the kind, I set it down as an ocular deception, and the thing passed entirely from my mind. But in March of this year (see No. 111), I was surprised, one evening, at seeing the Zodiacal Light fade sensibly away, dimmed to almost nothing, and then gradually brighten again. This was repeated several times; but the effect, after all, was to leave me only in amazement and doubt; subsequent nights, however, gave abundant exhibitions of this kind, of which, with the times and changes, I have

made ample records with the particularity which the case required. It was a great satisfaction, after my return home, to find that Baron Humboldt had observed the same thing while in southern latitudes, though he thought it more probable that it was owing to 'processes of condensation going on in the uppermost strata of air, by which the transparency, or rather the reflection of light, may be modified in some peculiar and unknown manner.' My records, however, will show that there is a regularity of appearance at the closing off of these pulsations, which proves that they do not belong to so uncertain a cause as atmospheric changes, but to the nebulous substance itself. They seem to intimate a great internal commotion in the nebulous matter, for they were too rapid to be occasioned by irregularities in its exterior surface.

"I noticed them again the following year, but must refer the reader to my records and charts. The changes were a swelling out, laterally and upwards, of the Zodiacal Light, with an increase of brightness in the light itself; then, in a few minutes, the shrinking back of the boundaries, and a dimming of the light; the latter to such a degree as to appear, at times, as if it was quite dying away; and so back and forth for about three-quarters of an hour; and then a change still higher upward toward permanent bounds."

(93) That these pulsations should be real seems not incredible in the instance of a substance having, as it would seem, a density even less than that of the material which exhibits the rapid changes of intensity, etc., of the aurora borealis. The girdle, moreover, would have a very nearly constant position with respect to the earth and the moon—*both magnetic*; and the earth in a relatively rapid *rotation*.<sup>1</sup>

(94) It would seem most probable that the middle plane or equator of the girdle should nearly coincide with the plane of *the moon's orbit*; but even in that case, the more intense illumination by transmitted light would be in directions nearly parallel to the plane of the ecliptic. That, and the local illumination, (75), ascertained and described by Mr. Jones, would together make it difficult to determine where the middle plane may be situated; though some observations of the "gegenschein" might seem to make it the same with the plane of the moon's orbit.

The position of the vertex of the Zodiacal Light would need to be more carefully scrutinized, and compared with that condition.

Such being the state of things, observations for *parallax* must, withal, most probably continue to be unsuccessful.

(95) As a summation of the consistencies of the hypothesis of a nebulous girdle revolving around the earth in the same time and general direction with the moon, and exhibiting the phenomena of the Zodiacal Light, we have:—

1. That it provides a conservative force for the maintenance of such an appendage.

---

<sup>1</sup> But it would be more difficult to understand and account for these special phenomena presented by the material in question, if it were directly a solar, instead of a terrestrial, appendage.

2. It will account for the phenomena common to all appearances of the zodiacal light, *broad base* and all.

3. It accounts for certain periodical changes in form and intensity, etc., of the same, which seem to be completed in a synodical revolution of the moon.

4. It provides for the *gegenschein* in form and position; and possibly also for "a lunar zodiacal light."

5. It renders a plausible account of the fading, at times, and total disappearance of the Zodiacal Light.

6. It accounts for the absence of a determinate parallax of the girdle.

7. It shows why, when east and west zodiacal lights are visible at the same time, the middle, even, of the zodiacal arch need not be wholly obscured by the earth's shadow.

8. It provides for the "pulsations."

#### *Origin of the Girdle.*

(96) It remains to consider how far the origin of the girdle may be accounted for by the modified nebular hypothesis, already so frequently applied.

If the moon herself were formed of a spheroidal shell [such as those described in (37)], while the form of the earth with its expanded atmosphere was yet very oblate; the equatorial diameter extending beyond the present distance of the moon—*i. e.* more than 60 times the radius of the earth's equator—the moon, derived from the atmosphere of this spheroid, might, at first, indeed have had the form of a spheroidal shell, with its equatorial circle nearly *in the plane of the ecliptic*, as the orbit of the moon now is, instead of *the plane of the earth's equator*, since *determined*.

This whole collection of material having, by processes heretofore described, (26), been brought to revolve together, the outer portions having thereafter failed to be collected with those that went to form the moon herself, these same outer portions would still continue to revolve and complete the same periodic time.

The part between the moon and the earth would nearly all be compelled to fall toward the earth in obedience to her superior attraction; except, possibly, some small remnant still forming an extra-mundane nebulosity (the middle of it at the position *A* in *Fig. 13*); the existence of which might help to account for some of the phenomena of *solar eclipses*, if not also of those of *transits* of the inferior planets; which it would be out of place to enlarge upon in this connexion.<sup>1</sup>

(97) Whether the material which exhibits the *Aurora Borealis*, or rather *Aurora Polaris*, can have had a similar origin, near to the pole of the oblate expanded atmosphere, and so, also, near to the pole of the Ecliptic in direction, as well as actually near to the earth, can be little better than matter of conjecture. The results, of the spectrum-analysis [(74) and *Note*] do not yet establish a composition

---

<sup>1</sup> The present Astronomer Royal, Sir George B. Airy, is understood to have said, soon after the total eclipse of the sun, in 1842, that some of the phenomena of that eclipse required for their explanation the supposition of the existence of a material *between* the moon and the earth.

of this material similar to that of the Zodiacal Light. It may, however, be asserted that auroral phenomena are most intense in latitude *about* that of the arctic circle; in which region, it must also be remembered, we have the magnetic poles. It is withal true, that the Zodiacal light seems sometimes to have exhibited (like the Aurora) a *ruddy* tint. An instance is mentioned in (91).

*Saturn's Dusky Ring.*

(98) The situation of the dusky ring of Saturn somewhat resembles that of the zodiacal girdle (if supposed to be a terrestrial appendage). But the shape of the dusky ring is different from that of the girdle; and its position, concentric with that of Saturn [7 of (43) and *Note*], is maintained by the action of many satellites instead of one; the total action of the several bright rings on particles within being in every case *zero*. But the dusky ring besides is, as it were, *walled in* by the bright rings, which themselves are kept concentric with both the planet and the dusky ring.

*Of the Inclination of the Planes of the Orbits of the Planets and Satellites to the Equators of their respective Primaries; and the relative positions of their Perihelia and Nodes.*

(99) In a Memoir on the Secular Variations of the Elements of the Orbits of Eight Principal Planets, its author, Mr. John N. Stockwell, M.A., has given us the maximum and minimum inclinations of the planes of those orbits to the invariable plane of the solar system.<sup>1</sup>

From these and the inclination,  $7^{\circ}15'$ , of the plane of the solar equator to the plane of the ecliptic of 1850, as ascertained by Mr. Carrington,<sup>2</sup> we obtain the following approximate inclinations of the planes of the orbits to the plane of the sun's equator; carrying the reference back to that ancient state of things in which the nodes (of the same name), of the sun's equator and those of the planets' orbits in the invariable plane, respectively *coincided*.

| INCLINATION OF ORBIT TO SUN'S EQUATOR. |                                            |                                       |                                          |

<sup>1</sup> *Smithsonian Contributions to Knowledge*, vol. xviii, p. 169 of the Memoir in question.

<sup>2</sup> As quoted in Sir J. Herschel's *Outlines of Astronomy* (11th edition), (392).

It will be observed that when the planes of the orbits most nearly coincide with the invariable plane, they yet make an angle of nearly  $5^\circ$  with the plane of the sun's equator, except in the instance of Mercury, in which the inclination is scarcely  $1^\circ$ ; while the Earth and Venus, under the variety of circumstances here indicated, still, as it were, assert their *character as half-planets*, by preserving among themselves always nearly the same inclination.<sup>1</sup>

In view of our hypothesis all along kept in view, the question would here seem to be a pertinent one—Why so great an average deviation in the planes of the planetary orbits from the plane of the sun's equator?

The answer to this may, perhaps, be found in what has heretofore been insisted on; viz. the acquisition of material in the nebulous state from *extra-equatorial* portions of the sun's atmosphere; it being added withal that such an acquisition would not take place from both the northern and southern half-spheroids *at the same time*.<sup>2</sup>

The extra-equatorial acquisition, (37), of more dense material being thus mainly from one side, *that* has, it would seem, tended to produce an average deviation in the plane of the resulting orbit.<sup>3</sup> In that aspect of the matter, and, in view also of the *Ancient State* contemplated in (44) and in Table (F), it may not be entirely without significance that the color of Neptune is a pure white, while that of Uranus is inclined to yellow, and that of Saturn, the other component [as in Table (F)] is decidedly so. But Jupiter is, again, white, while Mars is ruddy, and the Asteroids are—Juno of a pale yellow color, and the others reddish.<sup>4</sup>

Then, again alternately, the half-planet Venus, and also our satellite are both white; while Mercury is nearly of a rose color.<sup>5</sup> In the case here supposed, it is

<sup>1</sup> With M. Sporer's value of the inclination of the sun's equator, the numbers in column 2d will be diminished  $18'$ .

<sup>2</sup> An examination of Mr. Trowbridge's paper, already referred to [*Notes* to (38) and (57) respectively], shows that he has wrought with the same idea in view; though he has applied it to the change in the solar axis of rotation.

<sup>3</sup> Unless, with Mr. Trowbridge, we say that "the invariable plane of the solar system must" (also) "be the invariable plane" for "the primitive solar spheroid, and that it must have coincided approximately with the plane of the sun's equator;" and so he compares the inclination of "the invariable plane" to the ecliptic with that of the orbit of Neptune, with which it nearly agrees. In such a case, with the average existing inclination of the plane of the sun's equator to those of the planetary orbits; it would seem that the sun's equator has itself changed its position; the vicissitudes being similar to those, (68), which, according to M. Laplace, the earth in its forming state seems to have undergone.

But it should here be borne in mind that the invariable plane has its position ascertained by a reference to the conditions of material as *now* accumulated into planets with well-determined orbits; and so the invariable plane thus conditioned may very possibly be not coincident with "the invariable plane of the *primitive* solar spheroid."

<sup>4</sup> *Le Ciel*, par Amédée Guillemin, 4ième Edit. pp. 283 and 284.

<sup>5</sup> Are the white planets, then, in part derived from the one half-spheroid, and the planets of another color from the other? and is the half-spheroid, which furnished the white series, the *northern* one? (?)

For, as respects the existing state of comparative activity in the two hemispheres of the sun, as indicated by the appearance of the solar spots, "a very material difference in their frequency and magnitude subsists in its northern and southern hemisphere; those on the northern preponderating

besides manifest that what would be the *ascending* node of the planetary orbit when, in such a case, the acquisition was from the one half-spheroid, would be the *descending* node in the instance of the other.

And with respect to the matter here brought into question, as well as in other aspects, though without deciding that they have any significant connexion; we may consider some of the relations developed by Mr. Stockwell, and exhibited in his *Memoir*; such as—

“The *mean motion of Jupiter’s node* on the invariable plane is exactly equal to that of *Saturn*, and the *mean longitudes of those nodes* differ by exactly  $180^{\circ}$ .”

The latter portion of that description may have some interest in this connexion.

Mr. Stockwell states, withal, that “The mean angular distance between the perihelia of *Jupiter* and *Uranus* is exactly  $180^{\circ}$ .”

These and other relations connected with them, are shown by Mr. Stockwell to be eminently harmonious and conservative; and then, after stating that he had prepared separate solutions corresponding to several increments of the Earth’s assumed mass; and that a comparison of the values which the different solutions give for the superior eccentricity of the Earth’s orbit “has suggested the inquiry whether there may not be some unknown physical relation between the masses and mean distances of the different planets.”<sup>1</sup>

After having withal arrived at the conclusion that “a system of bodies moving in very eccentric orbits is” . . . “one of manifest instability;” he says, “and if it can also be shown that a system of bodies moving in circular orbits is one of unstable equilibrium, it would seem that between the two supposed conditions, a system might exist which should possess a greater degree of stability than either,” and then indicates a superlatively grand problem, viz., that “The idea is thus suggested of the existence of a system of bodies in which the masses of the different bodies are so adjusted to their mean distances as to insure to the system a greater degree of permanence than would be possible by any other distribution of masses.” He adds: “The mathematical expression of a criterion for such distribution of masses has not yet been fully developed; and the preceding illustrations have been introduced here, more for the purpose of calling the attention of mathematicians and astronomers to this interesting problem than for any certain light we have yet been able to obtain in regard to the solution.”<sup>2</sup>

in both respects” [Sir J. Herschel’s *Outlines*, etc., (393)]. See, also, the enumeration and classification of solar spots, founded upon Mr. Carrington’s observations, as reported by M. Faye (*Comptes Rendus*, tome lxxvi, p. 393).

The white planets *Jupiter* and *Venus* seem to show in their atmospheres, *now*, traces of great activity, even such as could be consistent with a high temperature. As respects *Jupiter*, see again *Note 2* to (69).

<sup>1</sup> See pp. xiv, xvi, and xvii of the Introduction to the *Memoir*, respectively.

As to the existence of such a relation and also as to its connexion with the times of rotation of the several planets—see, again, *last Note* to (44); also *Article* (109), and *Consistency 61st* of the *Summation* in (110).

<sup>2</sup> See pp. xiv, xvi, and xviii of the Introduction to the *Memoir*.

(100) In the *satellite systems* we find the orbit of the outermost satellite of *Saturn* making an angle of about  $14^\circ$  with the plane of his equator and that of the rings, this angle being about one-half of that which the latter makes with *Saturn's* orbit, while the orbits of the other satellites are nearly in the plane of rings and the equator.

Then the orbit of *our own moon* has a mean inclination of something less than  $5^\circ 9'$  to the orbit of the *Earth*; while the variable inclination to the *Earth's equator* is more than four times as great; as though the moon in the nebulous state had been "abandoned" in the form of a spheroidal shell before the axis of the earth, (68), was established; and so with *Saturn's* outer satellite, under it may be even more disturbing circumstances, (43); while the orbits of the inner satellites and the rings of *Saturn*, having a later history, nearly coincide with the plane of his equator, the same being very nearly the case with the satellites of *Jupiter*; the outer one, notwithstanding, justifying its character as shown in Table (D) in (20), by exhibiting an inclination greater than that of either of the other three.

The orbits of the satellites of *Uranus* are nearly perpendicular to the plane of his orbit; and so that their motions are even retrograde; while the equator of the planet [3 of (43)], inclined at an angle of about  $79\frac{1}{3}^\circ$ , has its rotation direct; all exhibiting, as it would seem, the effect of the great transference of material to *Saturn*, described in (43).

And although, at present [see 3 of (43)], the equator is inclined to the orbits of the satellites at an angle of about  $60^\circ$ ; yet, if it be indeed allowable to refer the situation of all these to that very ancient time when the ascending node of the equator on the planet's orbit nearly coincided with the descending nodes of the orbits of the satellites, then all would be found approximating to a coincidence in the same plane, the several inclinations of all of them to the plane of the planet's orbit being now near to  $79^\circ$ ; but the direction of rotation of the planet the reverse of that of the revolutions of the satellites.

It might almost seem then, as if, in the great transference of material to the ancient *Saturn* here again spoken of, the rotation of the outer, and mostly rarer, portions of the mass had been most affected; so that, in the satellite-formation, the resultant rotation became even retrograde, while the condensing planet conformed to the usual result of a direct rotation; though (in what was apologetically characterized as the tilting up of this whole system) all were constrained to revolve in planes nearly at right angles to the planet's orbit, and all nearly in the same plane.

The satellite of *Neptune* revolves in an orbit having a large inclination to the plane of the planet's orbit, and the motion is retrograde; but whether that also marks the direction of the rotation of the planet's equator, does not yet appear; nor which direction, therefore (that of revolution, or that of rotation), might be regarded as having been established before the other.

## THE MINOR SYSTEM.

(101) After the separation of the great mass of Jupiter, the “abandonment of the solar atmosphere would seem to have again occurred more exclusively in the region of the solar equator; and thus the Asteroid-mass and Mars appear to have been separated; to be succeeded, in order, and with variety of constitution, by the Earth, Venus, and Mercury.

And so it would appear, on a smaller scale (*within more restricted limits* for the balancing of the centripetal and centrifugal forces), was constituted *that minor system*, which, *in fact*, resembles the whole great solar system, in the features and mode of constitution already traced in changes on the larger scale. A system, viz., in which the Asteroids and Mars, as far as may be, have the places respectively of Neptune and Uranus on the greater scale, and the Earth and Venus those of Saturn and Jupiter [the Earth, (39), greater than Venus, from the accession, from regions of the sun’s atmosphere other than equatorial]. After these Mercury [and possibly an interior planet], to have the place analogous to that of all the small planets (not Asteroids) in the great solar system.

*Resemblances and Differences between Saturn and the Earth.*

(102) It may not be without some interest to exhibit in connexion the resemblances and differences between Saturn and the Earth—the Saturn of this Minor System. These are:—

1st. In ancient times, an unusual oblateness of form, evinced [(43) and (96)] in the case of both planets by the great distances of their satellites; the outer satellite of Saturn, and also our own moon, being each at the distance of more than 60 radii of its own primary.

2d. Saturn and the Earth have each an abnormal density; that of Saturn being *too low*, it would seem, because of the absorption, (43), of the rare material, which would otherwise have constituted the half-planet interior to Uranus; but the Earth’s density, (39), being made abnormally *great* by the absorption of an extra-equatorial portion of the sun’s nebulous atmosphere.

3d. Each of these planets exceeds the other planets in the same region of the solar system with itself, in number of satellites. This is true, though the Earth has but one; but that is the only one in the Minor System.

4th. Saturn is surrounded by two systems of bright rings and a dusky ring; and the Earth [if we admit the existence of the Zodiacal Girdle, (78)] is surrounded by something analogous to the dusky ring of the other planet; though they differ from one another to some extent, both in form and position; and the one is preserved because the planet has *many* satellites, the other because its planet has but *one* such accompaniment. [See, again, 7 of (43), and (79) to (83) inclusive.]

5th. The Earth [2 of (39)] seems to have been instrumental in producing the great inclination of the equator of its interior half-planet Venus, and Saturn [3 of (43)] as efficient in producing a similar effect upon the half-planet exterior to itself, viz., Uranus.

(103) The analogies to the great planetary system, presented by the satellite systems, have been discussed, in another connexion and aspect, in (58) and (59).

*Possible Succession of Changes, in the Progress of the Division, Recombination, and Final Separation of the Great Masses of the Solar System.*

(104) In the *Ancient State* contemplated in (44) and in Table (F) in (45), the relation of masses and distances was, it would seem, very nearly the same with that of the existing masses and distances of Jupiter and of Saturn as exhibited in (53); viz., that in which  $m(r)^2$  of the one =  $m'(r')^2$  of the other.

For—retaining the symbols in (44)—[the second mass in order in Table (F) in (45), including in itself the masses of Uranus and Saturn, while the first mass is that of Neptune]; we have in the instance of the second mass

$$m'(r')^2 \text{ of } [(U)\hat{h}_2] = 0.05090861;$$

and for the first,

$$mr^2\psi = 0.0458582;$$

the ratio of the two being

$$\frac{m'(r')^2 \text{ of } [(U)\hat{h}_2]}{mr^2\psi} = 1.1101;$$

which, since  $mr^2$ , thus, nearly =  $m'(r')^2$ , gives

$$\frac{m}{m'} = \frac{(r')^2}{r^2};$$

or the masses nearly in the inverse ratio of the squares of the distances.

Next, comparing the mass and distance of Neptune—also those of the whole-planet (U), made up of *Uranus* and its (now) missing *interior half-planet*  $\hat{\text{e}}i$ —and then, the mass and distance of  $\hat{h}_2$ , that is of Saturn in its *ancient* state before, (43),  $\hat{\text{e}}i$  was absorbed [the mass of  $\hat{\text{e}}i$  being deduced as in (41)]; we shall obtain for the several ratios of the distances and the *inverse ratio* of the  $\frac{3}{4}$  powers of the masses, respectively:

$$\frac{\text{dist. of } \psi}{\text{dist. of } (U)} = 1.7770; \quad \frac{(m')^{\frac{3}{4}} \text{ of } (U)}{m^{\frac{3}{4}} \text{ of } \psi} = 1.7687.$$

$$\frac{\text{dist. of } (U)}{\text{dist. of } \hat{h}_2} = 1.7908; \quad \frac{(m'')^{\frac{3}{4}} \text{ of } \hat{h}_2}{(m')^{\frac{3}{4}} \text{ of } (U)} = 1.7125.^1$$

And then, with respect to the existing *Saturn* and *Jupiter*, we have, as in (53),

$$\left. \begin{aligned} m''(r'')^2 \text{ of } \hat{h}_2 &= 0.025985 \\ m'''(r''')^2 \text{ of } u &= 0.025832 \end{aligned} \right\};$$

a coincidence more perfect than that found in the instance of the two outer great masses, in which the data to be used are less accurately ascertained. Then here,

<sup>1</sup> It is at least curious that Saturn deprived of the mass of  $\hat{\text{e}}i$  (*i. e.* the *ancient* Saturn) must here once more enter into the computation instead of the existing planet.

of course, again, the masses are very nearly in the inverse ratio of the squares of the distances.<sup>1</sup>

The history of the changes would then seem to be:—

1. That the division of the great masses, *Neptune* and that composed of *Uranus* and *Saturn*, first occurred; in accordance with a proportion of masses and powers of distances, such as *Jupiter* and *Saturn* now present.

2. That *afterward* occurred the division of the compound *Uranus-Saturn* mass into the masses of the whole-planet (U) and the *ancient Saturn*  $\hat{h}_2$ .

3. That *subsequently to that*, the material of the whole-planet (U) was rent [the outer half-planet *Uranus* possibly falling inward somewhat, to justify the new equilibrium of forces];<sup>2</sup> and, (43), the material of the *inner* half-planet  $\hat{s}i$  passing over and combining with the *ancient Saturn*  $\hat{h}_2$ , to form the mass in part of the existing *Saturn*  $\hat{v}_2$ .

4. That, *before the planetary character of Saturn was complete*, the mass [derived in great part, it may be, from the atmosphere of the other half-spheroid of the sun],<sup>3</sup> which was to form *Jupiter*, became temporarily *blended* with the *Saturn-mass*; to be in the end separated in accordance with the same law of arrangement of masses and distances which, at first, was prevalent in the instance of the great masses, *Neptune* and the combination of *Saturn-Uranus*.<sup>4</sup>

(105) It will be observed, that the preservation of the continued equality of ratios here in question, depends upon the introduction, in one connexion, of the *ancient Saturn*, that is Saturn deprived of the very mass acquired by the process which brought about the disappearance of the mass of the *interior* half-planet  $\hat{s}i$ , as the same is described in (43) and (44), and the proof of which is manifold; while the preservation of an equality of ratios in another connexion is as truly dependent on the introduction of the *whole* mass of the *existing* Saturn.

Such are the facts; and no explanation appears, except that of the process which bore away the mass of the *interior* half-planet, the reality of which seems thus, again, to be confirmed; to which, possibly, may be added the mode of subsequent combination and separation suggested in (104).

Then we have the negative evidence, that the supposititious separation of the great masses in question in any other way, is not found to yield at all similar proportions.

#### *Kirkwood's Analogy.*

(106) This Prof. Daniel Kirkwood communicated to the *American Association* for the Advancement of Science in 1849.<sup>5</sup>

He first speaks of what, (39), we have described as the neutral point.

Thus, as Prof. Kirkwood states it (and the same is applied to the Earth in our

<sup>1</sup> The *existing* and *not the ancient* Saturn appearing here.

<sup>2</sup> Sec 5 of (43).

<sup>3</sup> See (99) and *Note*.

<sup>4</sup> In this connexion—see, again, *Articles* (56) and (57).

<sup>5</sup> *Proceedings*, p. 208.

figure): "Let  $P$  be the point of equal attraction between any planet and the next interior, the two being in conjunction;  $P'$  that between the same and the one next exterior.

"Let also  $D$  = the sum of the distances of the points  $PP'$  from the orbit of the planet" (the whole  $PP'$  in the figure); "which I shall call the diameter of the sphere of the planet's attraction.

" $D'$  = the diameter of any other planet's sphere of attraction found in like manner.

" $n$  = the number of sidereal rotations performed by the former during one sidereal revolution round the sun.

" $n'$ , the number performed by the latter; then it will be found that

$$n^2 : n'^2 :: D^3 : D'^3; \text{ or } n = n' \left( \frac{D}{D'} \right)^{\frac{2}{3}}$$

From this we shall have, alternately,

$$n^2 : D^3 :: n'^2 : D'^3; \text{ i. e.}$$

$$\frac{n^2}{D^3} = \frac{n'^2}{D'^3} = a \text{ constant.}$$

The coincidence with fact is very close in the several instances of *Venus*, the *Earth*, and *Saturn*.

The proportion thus exhibited is *analogous* to Kepler's 3d Law; that the squares of the periodic-times of the planets are as the cubes of their mean distances from the sun; and it is hence called *Kirkwood's Analogy*.

An "Examination" of this by the late Sears C. Walker is also given in the *Proceedings of the American Association* for 1849 (pp. 213 to 219 inclusive), and its consistency with *Laplace's Nebular Hypothesis* made the subject of comment.

*Failure of the Analogy in the Case of Uranus.*

(107) Conceding that the time of rotation of Uranus [3 of (43)], as found by W. Buffam, Esq., viz. 12 hours  $\pm$ , is a first approximation to the truth; Kirkwood's Analogy will be found to fail in the case of Uranus.

For if we apply Mr. Walker's formula, in which  $\theta$  represents the time of rotation (a mean solar day of the Earth being = 1);  $a$ , a planet's mean distance from the sun; and  $D$ , the diameter of the (Kirkwood) sphere of the planet's attraction; then,

$$\theta = \left( \frac{a}{2D} \right)^{\frac{3}{2}}$$

and we shall find, with the values of masses and distances as given in our Table (A), in (3), that, in the instance of Uranus,

$$\theta = 1^d.30380+ = 31.291 \text{ hours.}$$

instead of nearly 12 hours; the result of the observation already quoted.

But even this negative result seems almost like a *shadowing forth of the catastrophe*, which happened when the material of the half-planet interior to *Uranus* [(43) etc.] passed over to Saturn; which has so often asserted itself in our preceding investigations.

With the half-planet restored to its place [its distance as in Table (B), in (14), and its mass, as in (41)], we shall have, by a comparison of Uranus, with that and with Neptune, and the application of the formula,

$$\theta = 31,883 \text{ hours};$$

agreeing nearly with the former result.<sup>1</sup>

But if we combine Uranus and the restored interior half-planet, in a whole-planet arrangement at the whole-planet limit (U) in Table (B), in (14); we shall have (by a comparison with Neptune and the *ancient Saturn*  $\zeta_2$ , and the application of the formula) for the time of rotation of whole-planet (U),

$$\theta = 16.451 \text{ hours.}$$

Was there, then, in the collection of material adapted to form a whole-planet at limit (U), the origination of a moment of rotation of the remaining half-planet Uranus, which was not all destroyed when the interior half-planet mass passed over to Saturn??

All this is not for a moment to be insisted upon; but there seems to be a possibility that the failure of the *Analogy* in question, may, in this case, be due to these special conditions here also appearing as if in question; as they have been heretofore.

#### *Approximate Result in the Case of Mars.*

(108) In the application to the case of Mars, we may make use of the relative asteroid-mass as made out in (46); viz., 0.58929 of the mass of Mars.

Then, as in (60) the indications were in favor of a half-planet arrangement of the asteroid-mass, we have—distributing the mass [Note to (51)] in accordance with *that*—the *interior* half-asteroid mass = 0.33745 of the mass of Mars; and the distances withal [in accordance with the *Laws* found in (10)] being derived from those in the region in question (viz., *Saturn to Mars* inclusive), as exhibited in (12).

From these and the masses, on the one side, and the mass and distance of the Earth on the other, we may then obtain *D*, the diameter of Mars's sphere of attraction; and then, Mr. Walker's formula,

$$\theta = \left(\frac{a}{2D}\right)^{\frac{3}{2}},$$

will give for Mars's time of rotation 27h. 34m. 8.<sup>2</sup> Observation gives 24h. 37m. 4. The coincidence is as close as could be expected; the masses being more or less uncertain, and the formula confessedly "approximate."

<sup>1</sup> For the interior half-planet  $\zeta_2$ , if it ever had the planetary form and state, the time of rotation would be 33h. 982.

<sup>2</sup> Deriving the distances from the more extended series in the column of Law in Table (B), in (14), we have 27h. 46m. 3, for the time of rotation.

[With a *whole-planet* arrangement of the asteroid-mass, the resulting time of rotation of Mars would be 19h.968; the half-planet arrangement of (60), thus appearing again as preferable.]

So that, in the case of the asteroids, although the component material has been dispersed; yet, as a half-planet portion has not passed over and been absorbed by an interior planet, the determining conditions of the next interior planet's rotation have, it would seem, not been entirely disturbed.

*Of "Bode's Law," and the reasons for its success in the approximate determination of the respective distances of Uranus and several other planets, and also for its failure to determine the distance either of Saturn or that of Neptune.*

(109) The most simple statement of the (so-called) Law of Bode (or of Titius) is that of Sir J. Herschel; viz.: . . . . "The interval between the orbits of the Earth and Mercury is nearly twice that between those of Venus and Mercury; that between the orbits of Mars and Mercury nearly twice that between the Earth and Mercury; and so on."<sup>1</sup>

Now, (13), the mean value of our whole-planet ratio is (stated here approximately) 1.8. But, if we subtract Mercury's distance from each of two successive terms in the whole-planet series, to obtain the *intervals* between orbits here in question, the ratio of the remaining intervals will exceed the ratio  $r$  of 1.8+, since the smaller of the two distances compared will be *more than proportionally* diminished by such a subtraction; and the value of greater divided by the less (*i. e.* here of the ratio) will be *increased*. Thus:—

$$\frac{\text{Asteroid limit (A)}}{\text{Mars' distance}} = 1.8 +$$

But

$$\frac{\text{(A)} - \text{Mercury's distance}}{\text{Mars' distance} - \text{Mercury's distance}} = 2 +;$$

the ratio being a very little greater than that which "Bode's Law" requires.

The same ratio is, even, very well justified in the instance of the Earth compared with Venus, and Mars with the Earth; though [as exhibited in Table (B) in (14)], while the ratio of the distance of Venus to that of Mercury is (incidentally) the whole-planet ratio  $r$ , that of the Earth's distance to that of Venus is only  $r^{\frac{1}{2}}$ , and even the ratio of Mars' distance to that of the Earth is only  $r^{\frac{1}{2}}$ . But the increase of the measuring unit in the comparison, as we proceed, and the subtraction of Mercury's distance in every instance (one being more effective in the one case, and the other, in the other) together make the one interval near to the *double* of the other.

The ratio, as has been already stated, nearly accurate for the Asteroid-*interval* in the middle of the whole-planet series. But, when we pass beyond that to the Jupiter and Saturn terms, successively, the subtraction of only Mercury's distance, though just about sufficient for the justification of the Jupiter interval, gives a result *too small* in the instance of that of Saturn.

---

<sup>1</sup> *Outlines of Astronomy* (11th Edition), (505)

Thus—making use of the veritable distances as stated in Table (B), expressed approximately, we shall find:—

$$\frac{\text{Jupiter's distance} - \text{Mercury's distance}}{\text{Asteroid distance} - \text{Mercury's distance}} = \frac{4.81}{2.43} = \frac{1.98}{1}$$

But

$$\frac{\text{Saturn's distance} - \text{Mercury's distance}}{\text{Jupiter's distance} - \text{Mercury's distance}} = \frac{9.15}{4.81} = \frac{1.90}{1}$$

The same process would fail notoriously in the case of the next whole-planet (U), were that yet to be found. But Uranus being an *exterior* half-planet, the ratio of its distance to that of Saturn is  $r^{\frac{1}{2}}$  instead of  $r$ ; and so the double interval for Uranus is tolerably well preserved in comparison with that of Saturn.

But as the ratio of Neptune's distance to that of the *exterior* half-planet Uranus (though on a larger scale than that immediately preceding, in the order here pursued) is only  $r^{\frac{1}{2}}$ , the subtraction of only Mercury's distance from each of the others, leaves the interval for the greater in a ratio to that for the less of not more than  $\frac{1.62}{1}$ ; and so, the representative number when it ought to be 301 appears in the series of numbers illustrating the "law" as 388.

The latest application of "Bode's Law" would seem to be that of Maxwell Hall, Esq.; an abstract of whose communication is given in the *Monthly Notices of the Royal Astronomical Society*, vol. XXXIV, No. 7 (May, 1874), under the title of "*The Solar and Planetary Systems*."

The author states "Bode's Law" as follows: "In the solar and planetary systems the mean distances of the planets do not greatly differ in value from the terms of the series:

$$4\lambda, 7\lambda, 10\lambda, 16\lambda, 28\lambda, 52\lambda, 100\lambda, 196\lambda, 388\lambda, \text{ etc.},$$

where  $\lambda$  has different values in different systems. But there may be more than one, or there may be no planet or satellite near any of the above theoretical distances."<sup>2</sup> And he then proceeds to determine  $\lambda$  in miles for the planetary system, and for the Jovian, Saturnian, and Uranian satellite-systems respectively.

"Some of the numerical coincidences are very close; thus in the Uranian system, taking the distances to be  $7\lambda$ ,  $10\lambda$ ,  $16\lambda$ , and  $28\lambda$ , the first three satellites give  $\lambda = 17600$ , and  $17100$ , and  $17600$  miles respectively (but the fourth satellite gives  $\lambda = 13400$  miles)."<sup>3</sup>

"He then states a second proposition: 'Twice the unit of length in any system

<sup>1</sup> Accordingly in the statement of the "Law" as not unfrequently made, which represents the successive distances by the numbers 4,  $4+1 \times 3$ ,  $4+2 \times 3$ ,  $4+2^2 \times 3$ , etc., Saturn's representative number exhibits a conspicuous failure. For instead of the true number 95, the distance is represented by 100; the veritable distance—as has, in effect, been stated—being too *small* to conform to "Bode's Law."

[The representative numbers 4, 7, 10, etc., appear in Mr. Hall's series, quoted in this *Article*.]

<sup>2</sup> Especially in this connexion, see *Note* to (7).

<sup>3</sup> What has already been stated in the way of exposition of the application of this (so-called) law in the planetary system, and an inspection of our Table (E) in (21), with its *two* ratios in accordance with veritable laws, will at once show the reason for this discrepancy. See also *Note* to (7).

is approximately equal to that distance which corresponds to the period of rotation of the central body of that system,' or say"

$$\lambda = 1580M^{\frac{1}{3}}P^{\frac{2}{3}},$$

where  $M$  = mass of central body, in terms of the mass of the earth,  $P$  the period of the axial rotation in hours,  $\lambda$  in miles as before.

It thus appears that dividing the value of  $\lambda$  for any system by the value of  $M^{\frac{1}{3}}P^{\frac{2}{3}}$  for the central body of the system, the quotient should be 1580. For the Solar, Jovian, and Saturnian the quotients are 1790, 1340, 1720, mean 1620. For the Earth  $\lambda = 13100$ ; so that regarding the Moon as a fourth satellite (the three interior ones missing) the theoretical distance is 210,000 miles.<sup>1</sup>

The paper concludes with some considerations as to M. Lescarbault's planet *Vulcan*.

[Sir J. Herschel, in a *Note* to Article (505) of the 11th edition of his *Outlines of Astronomy*, makes the following statement:—

"Another law has been proposed (in a letter to the writer, dated March 1, 1869), by Mr. J. Jones, of Brynhyfryd, Wrexham. If the planets' mean distances from the sun be arranged in the following orders: Mercury, Venus, Jupiter, Saturn; the Earth, Mars, Uranus, Neptune; the product of the means in each group is nearly equal to the product of the extremes.

$$\frac{\text{Venus} \times \text{Jupiter}}{\text{Mercury} \times \text{Saturn}} = \frac{\text{Earth} \times \text{Neptune}}{\text{Mars} \times \text{Uranus}} = 1.$$
 In point of fact the first fraction = 1.02, and the last =  $\frac{1}{1.03}$ , so that the approach to verification of the law is really very near."

Now the first fraction

$$\frac{\text{Venus} \times \text{Jupiter}}{\text{Mercury} \times \text{Saturn}},$$

may be resolved into

$$\frac{\text{Venus}}{\text{Mercury}} \times \frac{\text{Jupiter}}{\text{Saturn}}.$$

An inspection of the ratios exhibited in our Table (B), in (14), will show that the first of these component fractions expresses a whole planet ratio  $r$ ; and the second component the *inversion* of that,  $\frac{1}{r}$ . So that the value of the whole expression

$$\frac{\text{Venus} \times \text{Jupiter}}{\text{Mercury} \times \text{Saturn}}, \text{ resolved into its two components here specified} = \frac{r}{1} \times \frac{1}{r} = 1.$$

Then the other fraction,  $\frac{\text{Earth} \times \text{Neptune}}{\text{Mars} \times \text{Uranus}}$ , may be resolved into  $\frac{\text{Earth}}{\text{Mars}} \times \frac{\text{Neptune}}{\text{Uranus}}$ ;

<sup>1</sup> The error is here nearly  $\frac{1}{3}$  of the quantity to be determined; whereas in our Tables (B) to (E), and even (F), inclusive, the greatest difference between veritable Law and Fact is that in the instance of Uranus, in which the discrepancy is not  $\frac{1}{30}$  of the quantity to be measured, and even for that [5 of (43)] a special reason is assigned. In almost every other instance the discrepancy is far less than that; indeed, all but incomparably small. The greater differences specified in Mr. Hall's paper are such as are characteristic of "Bode's Law."

and, from Table (B) again, we learn that the first of these component fractions expresses the *inversion* of an *exterior* half-planet ratio  $\frac{1}{r_i^{\frac{1}{2}}}$ , and that the second component expresses the *exterior* half-planet ratio  $r_i^{\frac{1}{2}}$  itself. So we have the value of  $\frac{\text{Earth} \times \text{Neptune}}{\text{Mars} \times \text{Uranus}}$  resolved into  $\frac{1}{r_i^{\frac{1}{2}}} \times \frac{r_i^{\frac{1}{2}}}{1} =$ , again, to 1.

The small differences from 1 (in the one way and the other) in the actual values already quoted, are due to the slight increase in the value of the ratio  $r$  (and its derivatives); as exhibited in our *Article* (13).

For the arrangement, otherwise, into the two "orders" here first quoted, there is no very manifest reason; and so it would seem to be merely artificial.†

#### SUMMATION OF COINCIDENCES.

(110) In the summation of coincidences and the comparison of the same with theoretical deductions, those will be first considered which have at various times been indicated by commentators on the nebular hypothesis of Laplace, beginning with those which M. Laplace has himself specified, and of which his hypothesis was especially designed to furnish the explanation.

1st. The motion of the planets in the same circular direction, and nearly in the same plane.

2d. The motions of the satellites, with few exceptions, in the same direction with those of the planets.

3d. The rotation of these different bodies and of the sun, also in that same circular direction, and in planes not much inclined to one another.

4th. The small eccentricity of the orbits of the planets.

5th. The hypothesis accounts for the existence of comets in the solar system, as well as the variety of inclination of their orbits; also for the very great eccentricity, and the change in the form of the same. See (34), and Note VII of the *Système du Monde*.

[M. Laplace's expansion and explanation of these five coincidences is exhibited in our *Articles* (24) to (34) inclusive.]

6th. The hypothesis accounts for Saturn's rings, (28), and that they also revolve in the same circular direction with the planets and their satellites.

7th. Asteroids as well as ordinary planets are provided for; as is explained in (29).

8th. The great heat of the sun and, possibly also, of some of the existing planets, are facts in place.

† Though it is also *curious* that we have, in both the instances in question, the product of the expressions of *white* planet distances, divided by that of those which are not of that description; the reason for the classification of the planets in that respect even, having (99), at least a quasi-relation to the *Ancient State* of the system exhibited in Table (F), in (45); which is again related (in the connexion in question) to the *more recent* arrangements exhibited in Table (B), in (14).

[See in this connexion (69) and its *Note*<sup>2</sup>. The seeming perturbations of the atmospheres of *Venus* and *Mercury*, and even those of the atmosphere of Jupiter, are also consistent with the supposition of a high temperature.]

9th. The very existence of a gaseous or nebulous envelope of the sun, as well as of the atmospheres to so many of the planets, is itself consistent with the hypothesis in question. [Confirmed by recent investigations with the spectroscope.]

10th. Another evidence of previous high temperature, as the hypothesis would require, is found in the internal heat of the Earth, even now.

11th. Similar is the evidence of geological facts; many of which require the existence of a very high temperature in ancient times.

12th. The evidences of the effects of a former high temperature in the moon, supplement the evidence of geology.

13th. The hypothesis accounts for the lack of an atmosphere to the moon; in the explanation quoted in (69).

14th. The hypothesis, in like manner, accounts for the absence of secondary satellites (satellites of satellites); and also shows why there are no secondary rings; in the explanation quoted in (68).

15th. The hypothesis accounts for the arrangement by which the moon and (it may be) the other satellites, present the same faces severally to their respective primaries; the explanation being that quoted in (68).

16th. The hypothesis accounts for the *spheroidal form* of the planets; they having been supposed to have been, in older times, in a gaseous or in a liquid state, in which they took a form suited to the rotation of their gravitating material. The researches of Prof. H. Hennesey "have shown that the ultimate ellipticity" in consequence of the accumulation of water, etc., in the equatorial regions, and the gradual abrasion of polar continents in case the Earth were *at first* a *solid* sphere, would be  $\frac{1}{404}$ , instead of "that found by actual measurement;"<sup>1</sup> viz, a little greater than  $\frac{1}{310}$ . The *Earth* could not then have been solid at first. The oblateness of *Mars* seems to be too great; but it is supposed that the liquid surface of some planets was solidified before they could assume the figure appertaining to their rotation.

17th. The molecular constitution and whole composition of *aerolites*; so like, and yet in some respects so different from, what we find on the earth, is consistent with a common origin of all from the ancient solar atmosphere. [The spectrum-analysis has, within a recent period, afforded similar testimony, and to a greatly enlarged extent].

[The existence of the Zodiacal Light is also consistent with the hypothesis in question. This consistency is not numbered here; as it must appear in another connexion.]

---

<sup>1</sup> As stated by Prof. Kirkwood.—*American Journal of Science and the Arts*, for Sept. 1860, p. 167.

18*th*. We have Kirkwood's Analogy; already discussed [(106) to (108) inclusive].

19*th*. It is consistent with Laplace's Nebular Hypothesis that the large planets should be furnished with satellites, while the small planets are not so attended, with the bare exception of the Earth; which, even, has but one, unless some small bodies, not wholly unlike aerolites, are to be added to the number. The "abandonment" of nebulous rings, etc., could more readily proceed and be carried to the result of condensed rings, or of satellites, in the case of the larger bodies.

20*th*. The greater density of the smaller planets in comparison with the larger; and the tendency to a law of increase from without inward, in the whole series; as manifested in Table (A) in (3). The decidedly abnormal deviations from this are specially accounted for. [See references in exposition of Consistencies 32*d* and 39*th* respectively.]

21*st*. The Nebular Hypothesis furnishes M. Laplace with an explanation of the exact commensurability of the angular motions, and thus of the periodic times, etc., of Jupiter's satellites; they having "immediately after their formation not moved in a perfect vacuum." The action, in this case, of a resisting medium, itself consistent with his hypothesis, is illustrated by M. Laplace in the way already indicated in (67).

The farther summation of consistencies will have special reference to other phenomena and relations discussed in this paper.

22*d*. In addition to Consistency 21*st*, we have an approximate commensurability of periodic times of some of the *satellites* of Saturn, and also of those of the *four outer planets* of the *Solar System*; as detailed in (67).

23*d*. The modification of the Laplace Nebular Hypothesis, (37), providing for spheroidal shells, provides, also, for a conservative force for the holding together of great masses; and so prevents the indefinite multiplication of asteroids in all regions of the system.

24*th*. As if in consistency with a common origin and mode of development, we have the three laws of distances of planets and half-planets, as stated in (10); and the arrangement in accordance with these, in Table (B), in (14).

25*th*. We have also the prevalence of similar laws in the *System of Saturn*; the arrangement in accordance with which is exhibited in Table (C) in (18). Then, moreover, we have the arrangement in so far as a more restricted system would admit (viz., in accordance with two such laws) in the *System of Jupiter*; as shown in Table (D) in (20); and in the approximate arrangement of the *System of Uranus* in Table (E) in (21).

26*th*. The gradual and systematic increase or diminution, as the case may be, of the leading ratio, and its powers in these several systems, would seem again to indicate that the arrangement had a *physical* origin, not unlike that under discussion. [See the Summing up of these relations in (22).]

27*th*. The consistency of the results obtained in so many connexions by a reference of positions to the *centres of gyration* of the revolving masses, together with other

facts in the same connexion, all but *insist upon and require* that the masses in question must have turned around *together*. [See especially the application of this in (39) and (41); also (44) with Table (F) in (45); and (53), (54), (56), and (104).]

28th. The conditions involved in connexion with what is stated in Consistency 27th, also show that the law or laws of apportionment of the masses are not independent of the laws of the distances; but that they are *functions*, one sort of the other. [See, again, last *Note* to (44); also quotations in (99), and *its last Note but one*.]

29th. It is in perfect agreement with Consistency 26th and 27th, if not also with Consistency 28th, that the *rings* of Saturn referred to their respective *centres of gyration* have, in Table (C), in (18), the places of *satellites*.

30th. We have, besides, the commensurability of the periodic times of the two great satellites of Saturn with those due to some of the limits of Table (C) in (18), at which satellites are now missing, as that commensurability is exhibited in (66), and in consequence of which (in view of the Laplace Hypothesis, or of that hypothesis as modified) the existence of satellites may have been prevented there; and thus also possibly may have been occasioned the space between the two systems of Saturn's bright rings; all, as explained in (64).

31st. Again we have the commensurability of the periodic time of *Jupiter*, and some of the periodic times due to certain of the *asteroid limits*, and also that of *Mars*; which may have been the means of breaking up former planets or asteroids, as is also explained in (64). With respect to the special relations of the *half-planets*, Earth and Venus—in accordance with the Laplace Nebular Hypothesis, or else with the same modified as in (37), we have:—

32d. The abnormal density of the Earth accounted for (a density too great for the Earth's place in the system). [See 1 of (39).]

33d. In connexion with that, we have the great inclination of the equator of the other half-planet Venus to the plane of its orbit; apparently accounted for in 2 of (39).

34th. We have the approximate agreement of the neutral point (the Kirkwood limit of the Earth's sphere of attraction between the two half-planets on that side) with the *whole-planet* limit for the combination of the two masses; as exhibited in 4 of (39). [The approximation to an agreement also of this last with the centre of gyration of the two half-planets has already been adverted to in the exposition of Consistency 27th, and its reference.]

35th. The great *oblateness* of the nebulous Earth (with its accumulated dense material) is, (96), recorded in the great distance of the moon, = to full sixty equatorial radii of its primary planet.

36th. That the ascertained *density* of the moon should be but 0.55654 of that of the Earth is another fact in place in this discussion, in view of Consistency 35th.

In consistency with the rest, and in confirmation of our subsidiary hypothesis accounting for the disappearance of the now-missing half-planet, which should be

found interior to *Uranus*; viz., that its mass was absorbed by what previously constituted the mass of *Saturn*, we have:—

37th. That the mutual attractive force of the missing mass and the *then-existing* *Saturn* was adequate in measure to the effect supposed; as is explained in 1 of (43).

38th. That the limit to which the same mutual attraction extended is itself not very far short of the limit (U) at which the *whole-planet* mass would be likely to be rent; as in the Earth-Venus case [4 of (39)]; as is farther explained in 2 of (43).

[The mass of the missing planet is found in (41) by the application of the formula for the centre of gyration; which has its reference in Consistency 27th.]

39th. The very *inferior density* of *Saturn* [below that due to his place in the system, and the least in all the series of densities of planets in Table (A) in (3)], is here a special fact in place; so much of the material of the existing *Saturn* being derived from the region *outside*. [See 4 of (43).]

40th. All this would contribute to give the forming nebulous *Saturn* a *very oblate* figure; the ellipticity being even greater than that of the forming Earth—for the outer satellite *Japetus* is at the distance of more than sixty-three radii of its primary; and the very faint light of that satellite in certain positions may be accepted as one condition not in itself inconsistent with a low density.

41st. All this would permit the formation of *satellites* to begin and advance, some time before that of the rings; and so the *conservative* influence of the satellites be exerted, in those early times, to preserve those rings and keep them concentric with the shrinking planet; and thus make it possible for *Saturn* to be adorned with those remarkable appendages which make him an *instantia solitaria* in the system. [See explanations and quotations in 7 of (43) and its *Note 3*.]

42d. The great mass of the *ancient Saturn*  $\hat{\epsilon}$ , (notwithstanding its low density), would seem to have been efficient in bringing about the great inclination of the equator of *Uranus* to the plane of its orbit, as well as to that of the ecliptic, [and also that of the whole Uranian system, specially described in 3 of (43);] the whole so like the effect on the inclination of the equator of *Venus*, insisted on in Consistency 33d. Thus these two phenomena, so like, but which present themselves in regions of the system remote from one another, are found to be referable to the action of not unlike causes.

43d. The very considerable inclination of the Saturnian system (equator of the planet, rings, and orbits of satellites)—so unlike in that respect to the system of the other great planet *Jupiter*—would seem itself to be referable to the same disturbance which so *tilted up* the equator and all the system of *Uranus*.

44th. It is not inconsistent with all this, that on a comparison of the column of Fact with the column of Law in Table (B) in (14), *Uranus* would almost seem to have *perceptibly* fallen in; and *Saturn* perhaps have been drawn a little outward. [See 5 and 10 of (43)]. And it may be that Consistency 31st is also to be found here [see 9 of (43)].

45th. A like effect may be more distinctly traced in the system of *Saturn*, in the instance of the satellite *Hyperion*, which is just outside of *Titan*, the Jupiter of the system; as may be made apparent by a comparison of the columns of *Fact* and of *Law* in Table (C) in (18); which is withal explained in (66). That *Mars* also seems to have perceptibly fallen in by the acquisition of material from the asteroid mass is discussed in (65).

46th. The subsidiary hypothesis of the transference of the half-planet mass, is still farther and very remarkably confirmed by the ratios due to the *Ancient State* exhibited in Table (F) in (45), the *Uranus-Saturn* ratio of which is *not justified*, unless we also restore *Saturn* to its *ancient state*, by restoring also the missing planet to its legitimate place; and then combine that, the mass of *Uranus*, and also that of the *ancient Saturn*  $\hat{\zeta}_1$ , all at their common centre of gyration; and then the appropriate ratio in Table (F) is very scrupulously justified.<sup>1</sup>

47th. The conformity of the ratios of the *Ancient State* is itself a justification of the mass of the missing half-planet; that mass being independently determined in conformity to the condition, that the centre of gyration of that half-planet and *Uranus* should be the same with the whole-planet limit (U) in Table (B) in (14).

This value of the mass is still farther confirmed, in so far as may be, by the curious relations developed in (104); in which the mass of the *ancient Saturn*  $\hat{\zeta}_2$  (*Saturn* deprived of the mass of the now-missing planet) enters in one connexion, and the mass of the existing *Saturn* in another.

48th. The justification of the ratios of the *Ancient State*, as the same are exhibited in Table (F) in (45), itself demands a special value of the asteroid-mass; and the value thus ascertained, with the data which we have, agrees closely with that signified by *M. Le Verrier* (in one of his investigations of the subject), as being required by the perturbations of the planet *Mars*. [See explanations and quotations in (47) and *Note*.]

49th. The arrangements of the *Ancient State* exhibited in Table (F) in (45), into which combinations of planetary masses alternately enter, justify the position of *Mercury* in their own series. Then withal the aphelion of *Mercury's* orbit has a whole-planet place in Table (B) in (14), while the perihelion of the same has a half-planet place. The arrangements of both tables thus consistently indicate that *Mercury* has accumulated in itself the material appropriate for a planet and a half planet, and that its position justifies that.

50th. The arrangements now specified, also serve to account for the great eccentricity of *Mercury's* orbit; the planet having absorbed into itself the ring-like or shell-like masses, one due to the whole-planet position at the aphelion of the orbit, and the other to the half-planet position at the perihelion.

---

<sup>1</sup> As the annual aberration of the sun, planets, and fixed stars is without explanation, if we do not admit the doctrine of the earth's motion; but the whole explanation is adequate in mode and in measure with that motion first admitted. There is certainly an approximation to a parallelism here.

51st. The distribution of masses which Consistency 50th would indicate, and the Laws of Distance in (10), together enable us to compute the mass and mean distance of material (possibly planetary) immediately interior to Mercury. And the mass thus indicated seems to be adequate to produce the perturbations of Mercury's orbit to the *extent required by M. Le Verrier*. [See discussion of all in (52)].

52d. With the arrangement of distances of *Jupiter* and *Saturn* either in the column of Law or in the column of Fact, in Table (B), in (14), and with the ascertained value of their masses, we find, (53), the *vis viva* or moment of (simultaneous) rotation of the one very accurately equal to that of the other; so that the masses are inversely as the squares of the radii of gyration; *i. e.* here inversely as the squares of the mean distances from the sun.

There is, at least, a rude approximation to the same, on a large scale, when the masses and distances of Neptune and the next term of the series [U $\hat{\eta}$ ] in Table (F) in (45) are, in like manner, made the subjects of a proportion in (104).

It may be then that the great divisions of the nebulous solar atmosphere (antecedent perhaps to other planet-forming developments) were made in conformity to the proportion here in question.

But in what seems like the subsequent subdivision of the [U $\hat{\eta}$ ] mass, in its special comparison with Neptune, the proportion, (104), of *distances inversely* as the  $\frac{3}{4}$  power of the masses is very accurately justified; in which the whole-planet mass (U) (consisting of the mass of Uranus and that due to its now-missing interior  $\hat{\delta}i$ ) enter, as well as the ancient Saturn  $\hat{\eta}$ ; though, as already intimated in Consistency 47th, the *existing* Saturn enters in the comparison with Jupiter.

The moments of (simultaneous) rotation of the outer and inner systems of bright rings of Saturn exhibit, (53), an approximation to equality like that of the great outer masses here spoken of.

[Also if the expressions of the respective velocities of the existing ring systems, at their centres of gyration be made to enter, instead of the 2d powers of the same, we have, (53), with  $m$  and  $m'$  for the masses, and  $a$  and  $a'$  for the distances from the centre of the planet

$$\frac{m \times a \text{ of inner rings}}{m' \times a' \text{ of outer rings}} = 1.0752.$$

Incidental very possibly, but curious.]

53d. From what is stated in Consistency 52d, it would seem to have been the case, that the large masses of the system, in the series from without inward, increased in a more rapid ratio than the respective distances diminished (in a more rapid ratio, *viz.*, than the inverse ratio of the distances); the increased density of material more than counterbalancing the effect of its diminished quantity.

Accordingly, in (57), with scarcely an exception, we find a continual increase of the masses, from Neptune to Jupiter inclusive; the mass of Jupiter being transcendently the greatest of all.

The like, (58), is true (Hyperion being the exception there) in the system of Saturn; Titan being the Jupiter of the system; as is, (59), the 3d satellite among the four satellites of Jupiter; while, lastly, the Earth and Venus, (101), are,

respectively, the Saturn and the Jupiter of the Minor System of planets; and there are other curious relations, furnishing subjects for comparison, which are detailed in (101) and (102).

54th. It is shown in (16) that the centre of gyration of a thin homogeneous ring is in the circumference of a circle concentric with the edges of the ring, and bisecting its area. Also that  $R'$  and  $r'$  being the radii of the edges of the ring and  $C$  that of the centre of gyration, we shall have

$$C^2 = \frac{1}{2}(R'^2 + r'^2).$$

(a) The same, in (54), is extended to the case in which the equivalent masses are both thin homogeneous rings, one wholly clasping the other;  $R'$  and  $r'$  representing the respective radii of the centres of gyration of the two clasping rings, and  $C$  that of the common centre of gyration.

(b) The common formula for the centre of gyration will, when reduced, give us the same equation, in the case of *any two equal* masses, irrespective of the form of either.

Now although the two systems of bright rings of Saturn can scarcely be presumed to be homogeneous, and although they do not seem to be equal in mass, yet, (55), the equation in question is found to be very nearly applicable to them.

[Making use of this *inductively*, as some indication of the ring-like form in revolving masses, (55), we found, that the like equation in the solar system was very nearly justified in the case of the half-planets Earth and Venus; and, (56), that a similar one was nearly realized in the case of Neptune and Uranus; the distances being those in the column of Law, in Table (B) of (14).<sup>1</sup>

These results might seem to be consistent with the supposition that the flowing over of the material of the oblate solar atmosphere had given to the masses in question, at some period of their development, a form not unlike that of a *thick ring*; and yet the same cannot be regarded as decisive; and in the case of Uranus and Neptune, there is the other explanation found in (b) of this Consistency; for the masses of Neptune and Uranus are nearly *equal*.]

In another and different instance we have a closer agreement.

The centre of gyration, (19), of the whole system of Saturn's Bright Rings is at a distance from the planet's centre = 1.9090; being just within the outer edge of the Inner Bright Ring (or Rings), which is at the distance 1.9276; as though the division of one great ring had taken place there.

Some reason why the opening between the system of rings should be permanent, is given in (64); which reason has already been alluded to in Consistency 30th.

---

<sup>1</sup> Before Uranus (Consistency 44th) had perceptibly *fallen in*.

55th. An application of the criterion of the ring-like form as stated in Consistency 54th, was, as far as might be, made use of [(60), (61), and (62)] in determining as to whether it would be preferable to attribute to the *asteroid-mass* (in the progress of its development) at any period, a whole-planet or a half-planet arrangement; without the assertion that either is, beyond controversy, supposable.

In favor of the supposition of a *half-planet* arrangement, we had:—

(a) That we do not find the equation here in question justified when a comparison is instituted between the whole-planet arrangement and Mars; but, with an appropriate distribution of the mass for a *half-planet* arrangement we find, (60), a close approximation to the fulfilment of the equation in question.

(b) This might seem to have the less weight, were it not also true that the limit of equal attraction between the exterior half-asteroid mass and Jupiter, (60), is 3.35790, and that between the interior half-asteroid mass and Mars, is 2.14438; which limits very well mark the *range* of the mean distances of the known asteroids; and, (61), the respective distances 3.34083 and 2.47748 of the exterior and interior half-asteroid masses approximate to the *aphelion* and *perihelion distances* of several of the existing asteroids; so that the case in that respect may possibly resemble that of Mercury, commented on in (50).

(c) Other circumstances discussed in (65), and referred to in Consistencies 31st and 45th, seem to indicate that (with the wide range and great eccentricity of the asteroid-orbits) Mars may have acquired material of slower motion; which caused that planet (*perceptibly*) to fall in. Such is the look, when Fact and Law in Table (B) in (14) are compared.

[This is again alluded to here because of its present connexion with the other considerations; though formally noticed in Consistency 45th.]

(d) Though we may not attribute too much weight to our results when the data are imperfect—yet, in this connexion, we find that the formula derived from Kirkwood's Analogy, which, (107), signally fails (for reasons assigned) to give us the length of the sidereal day of Uranus, yet, (108), approximates to a true result in the case of Mars, referred on the one side to the Earth and on the other to the interior *half-asteroid* mass.

56th. In view of the secular variations of the planetary orbits, we have exhibited in (99) the close approximation to coincidence of the planes of those orbits in very ancient times.

In (99) we make the suggestion that the mean inclination of the sun's equator (of nearly 5°) to these may have arisen from the fact that the acquisition of material of a planet from the extra-equatorial regions of the sun's nebulous atmosphere, may have been mainly from one side; the changes in the two half-spheroids not being *simultaneous*.

But this is a region for speculation in which our sources of information are very restricted. [Not quite discordant with it, however, is the fact mentioned in (99), and its Note (5), that the great planetary masses of Table (F) [in (45)] are alternately white and yellow or ruddy.]

57th. Other harmonies may be gathered from the *Memoir on the Secular Variations of the Elements of the Orbits of Eight Principal Planets*, by John N. Stockwell, M.A., from which the positions of the planes of the planetary orbits, alluded to in Consistency 56th, are taken; which harmonies are to some extent described in (99). These, like Consistencies 22d and 31st, seem to indicate a common origin of the bodies concerned—under restricted circumstances.

58th. As stated in (100), the orbits of the outermost satellites of Saturn and Jupiter have very considerable inclinations to the equators of their respective primaries; as though their development had an earlier history than that of the other satellites and appendages.

And the orbit of *our own moon* has a mean inclination of something less than  $5^{\circ}9'$  to the *orbit* of the Earth; while the variable inclination of the Earth's *equator* is more than four times as great; as though the moon in the nebulous state had been separated *in the form of a spheroidal shell*, before the axis of the Earth was established.

The like, withal, would seem, (100), to have happened in the instance of the satellites of Uranus and their primary planet: with additional varieties, themselves, as it were, confirmatory of the supposition of the rending away and absorption by Saturn of the *mass due* to the (now missing) half-planet, which was once connected with *that* of Uranus.

59th. In our explanation of the appearances of certain of Jupiter's satellites as dark spots, while they were in transit across the disk of their primary; the conclusion was arrived at, (69), that the phenomena were due to absorption, and possible interference, of the light proceeding from Jupiter and encountering that of the satellite; as is explained in (69). The circumstances also seemed to indicate:

(a) A confirmation of the supposition that the satellites, in their revolution, continue to present, respectively, each nearly the same face to its primary.

(b) That the phenomena of absorption, etc., indicate, as a reasonable probability, that the satellites are *colder* than their primary.

(c) That, therefore, the satellites, like our moon, have very possibly little or no atmosphere.

(d) That, in view of the Laplace Nebular Hypothesis, the satellites may, then, possibly have lost their atmospheres, in the same way in which M. Laplace supposes the moon's atmosphere may have been carried away; which was already alluded to in Consistency 13th, and explained in (69).

All this bears upon the question of a similar origin and development of all the bodies (comets excepted) of the solar system.

60th. In Articles (70) to (95) inclusive we have a discussion of the phenomena of the *Zodiacal Light*; which, in (78), are regarded (in modification of Chaplain George Jones's hypothesis) as due to a *girdle* encompassing the Earth. It is further indicated, in (79), that the girdle is preserved from destruction by having its periodic time coincident with that of the moon; and the limits of the girdle, (82), are computed in accordance with that subsidiary hypothesis, and the variations, (83), in the size of the girdle are distinctly stated. Also *tidal* actions at the ends of the

major diameter. Accumulations of material, or the contrary, must also exist, in the maintenance of the dynamical equilibrium *where* the central forces of earth and moon act at an angle with one another; somewhat, it may be, like that which appears in *Fig. 14*, at *Article* (80).

Examples of observed phenomena are afterwards given; and in (95) eight particulars are specified, in which the whole hypothesis seems, thus far, to be consistent with the observed phenomena.

The resemblances and differences of the Girdle and Saturn's *Dusky* Ring are stated in (98).

61st. The late Sears C. Walker in a personal communication to the author of this paper, made some years since, was understood to say, that he had computed what would be the time of rotation of the now existing Earth, if its material were given a ring-like form extending to the Kirkwood limits; and that he had found a year for the time of rotation, as the Laplace Nebular Hypothesis would require.

Prof. Benjamin Peirce, commenting on the explanation of the rotation of the planets on their axes, as deduced from the nebular hypothesis of Laplace, and reasoning especially with regard to Jupiter and Saturn, is understood to have "demonstrated, by a mathematical analysis of the movements of the particles constituting the liquid ring, that the velocities of the resulting rotations of those planets must be such as are actually observed." No authentic information of this, however, seems as yet to have been made public.

[Then Maxwell Hall, Esq., (109), would establish a connexion between the mass of a central body, sun or planet, and its period of axial rotation, and certain approximate ratios developed from the so-called Bode's Law.]

In the statement of Consistencies no allusion has been made to the coincidences in the times of revolution of the planets with the respective times of rotation of the sun with an atmosphere supposed to be expanded successively to the distances of the planets. Sufficient data for this are not attainable.

Other coincidences not sufficiently accurate have not been insisted on in the enumeration; and conjectures, like that in (97), with respect to the *Aurora*, cannot yet be verified. The giving of undue weight to the result, in any instance, has, withal, been carefully guarded against.

In view, however, of all the consistencies which have now been enumerated, the inquiry whether these *can all be incidental*, would seem at once to suggest its own negative answer.

But whether that, indeed, be so or no, a single additional statement should, if possible, once for all, be made emphatic:—

THE SPECIAL RELATIONS EXHIBITED IN SECTION II. (DESIGNEDLY STATED WITHOUT REFERENCE TO ANY THEORETICAL CONSIDERATIONS), AND THE OTHER PHENOMENA DETAILED IN SECTION III., AT LEAST IN SO FAR AS MERE NUMERICAL RELATIONS ARE CONCERNED—ALL THESE, FROM FIRST TO LAST, DEPEND UPON EXISTING FACTS OR RELATIONS IN THE SOLAR SYSTEM ITSELF; AND SO MUST ENDURE WHILE THE SYSTEM LASTS, THOUGH EVERY HYPOTHESIS WITH REGARD TO THOSE RELATIONS SHOULD BE REJECTED.

But if every hypothesis be rejected, the relations exist as more or less consistent, but yet as ultimate facts; *i.e.* without any explanation; while the hypothesis, or rather theory, which has been discussed in these pages, seems, with a more or less perfect applicability, to *include and grasp the whole*.

---

ADDENDUM.

*Consistency 62d.* In addition to what is already stated as a part of Consistency 55th, it may be noted, that the resulting rotation of Mars as determined by Kirkwood's Analogy, (108), is not merely, *in so far as may be*, confirmatory of the half-planet arrangement of the *asteroid-mass* exhibited in (60); but also of the *value* of the *mass itself*, as determined in (46): the appropriate fraction of the mass entering into the computation of the time of rotation in question.

---

NOTE (A).

*On the Origin of Clusters and Nebulæ.*

The application of similar principles to those involved in the Nebular Hypothesis of Laplace, but on a larger scale, and with reference to a greater variety of circumstances, led the author of this paper to his own hypothesis of the *Spheroidal Origin of Clusters and Nebulæ*; which represents those groups and conglomerations as being the derivations of spheroids (or of rings derived from spheroids, or of masses of an ancient ring-like form) all rotating in a state of dynamical equilibrium, at periods very remote. But, that the process of cooling brought about like phenomena to those which the Laplace-hypothesis maintains to have taken place in the instance of our sun; *viz.* the same more rapid rotation, sometimes with a local increase of actual velocity, sometimes with a diminution of the same; but always, on the whole, with an increase of angular velocity, continued, however, until the *centrifugal force of rotation overmastered cohesion and gravitation*, and, in place of an "abandoned" equatorial ring, portions of the ruptured material were *ejected*; to be left behind the others, in the direction *opposite* to that of the rotation—the material thus being broken into elongated fragments, and they again into drops; but every drop having in it material sufficient to form a condensed nebula, or in the end a star: the result presenting appearances such as are visible in the very beautiful nebula H. 1173; the spirals described and figured by the late Lord Rosse; the projections from the one end of the annular nebula in Lyra; and the teeth *leaning backward* in the globular cluster H. 1968, etc. etc.

The expositions in the communication here referred to, occupy in all twenty-nine (double-column) quarto pages of the 2d volume of (*Gould's*) *Astronomical Journal*,

published in 1852; and among those expositions is one, drawn out in detail, the heading of which is "*The Milky Way—a Spiral*;" which is found in No. 37 of the Journal specified, at p. 101; followed by some reasons for supposing that the spiral had four branches, and a dense central cluster.<sup>1</sup>

For a variety of other details as well as a more complete exposition of the phenomena and their progress, reference must be made to the memoir itself; but one of its concluding paragraphs should, if possible, be made emphatic; and, therefore, we also introduce it here. It reads thus:—

"While it is even to be expected that errors may hereafter be found in the various details which have been so fully exhibited, it is respectfully submitted whether this same hypothesis of the spheroidal origin of so many of the clusters and nebulae, in its most important features, is not adequate *in mode*; or whether, in the very least, the phenomena do not even *require* the admission of a *dynamical equilibrium destroyed*, as the one pervading principle—guiding, as it would also seem, to the explanation of all the other conditions."

It would seem, indeed, to be in vain to look for an exposition of the phenomena and their progress, if we do not keep in view and adhere to the hypothesis of a dynamical equilibrium *destroyed*; a *conservative* view does not *now* suit the case.

Among the conditions requiring just *that*, are the phenomena here briefly adverted to; and the fact that the centres of clusters do not exhibit the enormous condensation *anywhere*, which the "clustering power" of Sir William Herschel, it would seem, must *somewhere* have produced; but, on the contrary, the central portions uniformly appear as if, when they were released from superincumbent pressure, by the rupture of the outer portions of the spheroid, or other primitive form, their feeble central attraction could no longer preserve them in form; and so the centres are always broken up. The *sudden curvature of the spirals*, moreover, seems to be more like that due to the ejection of material under the influence of an excess of centrifugal force, than that which would result from a rushing inward, in obedience to an excess of attraction.

The supposition of original *nebulous* spheroids does not seem to be contradicted by the revelations of the *spectroscope*; but, on the contrary, to be consistent with them.

In further justification of an hypothesis, the distinguishing feature of which is the utter destruction, on the *large* scale, of a dynamical equilibrium, we also reproduce the conclusion of the communication already referred to, which is as follows:—

The more condensed clusters (other things being equal) must, upon this plan, be regarded as probably of the more recent origin; instead of being the older, as supposed by Sir William Herschel (*Phil. Trans.* for 1789, pp. 224 and 225); and if a continued dispersion is even yet in progress, the *permitted* collisions regarded

---

<sup>1</sup> This assuredly must have been overlooked, or else—though noticed—have been forgotten; or we would not find among the *Proceedings of the Royal Astronomical Society* (Dec. 1869), "A *New Theory of the Milky Way*, by R. A. Proctor, B. A.;" which describes and figures the Milky Way as being a *spiral*—though not, indeed, with four branches.

by Sir John Herschel [*Outlines of Astronomy* (872)] as quite supposable as consequences of the clustering power, will be the more frequently avoided; and stars, which, like our sun, may have planets in their keeping, will bear their attendants away beyond the reach of harm.

In view, then, of even the little that has yet been ascertained, may we not in all humility ask whether *this* was not indeed *the way* in which the SUPREME DISPOSER of both great and small events executed his vast purposes; the changes being, alternately, destructive and conservative.

For the growing leaf is fed by the exhalations which it finds in the atmosphere; and the leaf, in its decay, nourishes the vegetating tree; the roots of that tree are embedded in the *débris* of a comparatively ancient earth; the earth itself, in view of the nebular hypothesis (of Laplace), has been detached from the sun; and the sun and other stars would now seem to be but the comparatively small fragments or drops of greater masses: the one great plan pervading the *whole*, being, BY MEANS OF A PERMITTED DESTRUCTION, TO PROVIDE FOR A MORE PERFECT ADAPTATION AND DEVELOPMENT.

#### NOTE (B).

##### *Of the Nebular Hypothesis of Sir William Herschel.*

On this subject, Sir John Herschel says in his *Outlines of Astronomy*, (871):—“The first impression which Halley, and other early discoverers of nebulous objects received from their peculiar aspect, so different from the keen, concentrated light of mere stars, was that of a phosphorescent vapour like the matter of a comet’s tail, or a gaseous and (so to speak) elementary form of luminous sidereal matter. Admitting the existence of such a medium, dispersed in some cases irregularly through vast regions in space, in others confined to narrower and more definite limits, Sir W. Herschel was led to speculate on its gradual subsidence and condensation by the effect of its own gravity, into more or less regular spherical, or spheroidal forms, denser (as they must in that case be) towards the center. Assuming that in the progress of this subsidence, local centers of condensation, subordinate to the general tendency, would not be wanting, he conceived that in this way solid nuclei might arise, whose local gravitation still further condensing, and so absorbing the nebulous matter, each in its immediate neighborhood, might ultimately become stars, and the whole nebula finally take on the state of a cluster of stars. Among the multitude of nebulae revealed by his telescopes, every stage of this process might be considered as displayed to our eyes, and in every modification of form to which the general principle might be conceived to apply. The more or less advanced state of a nebula towards its segregation into discrete stars, and of these stars themselves towards a denser state of aggregation round a central nucleus, would thus be, in some sort, an indication of age. Neither is there any variety of aspect which nebulae offer, which stands at all in contradiction to this view. Even though we should feel ourselves compelled to reject the idea of a

gaseous or vaporous 'nebulous matter,' it loses little or none of its force." [The spectroscope indicates that *that* need not always be.] "Subsidence, and the central aggregation consequent on subsidence, may go on quite as well among a multitude of discrete bodies under the influence of mutual attraction, and feeble or partially opposing projectile motions, as among the particles of a gaseous fluid."

"(872) The '*nebular hypothesis*,' as it has been termed, and the *theory of sidereal aggregation* stand, in fact, quite independent of each other, the one as a physical conception of processes which may yet, for aught we know, have formed part of that mysterious chain of causes and effects antecedent to the existence of separate self-luminous solid bodies; the other as an application of dynamical principles to cases of a very complicated nature no doubt, but in which the possibility or impossibility, at least, of certain general results may be determined on perfectly legitimate principles."

"Among a crowd of solid bodies of whatever size, animated by independent and partially opposing influences, motions opposite to each other *must* produce collision, destruction of velocity, and subsidence or near approach towards the center of preponderant attraction; while those which conspire or remain outstanding after such conflicts, *must* ultimately give rise to circulation of a permanent character. Whatever we may think of such collisions as events, there is nothing in this conception contrary to sound mechanical principles."

"Ages which to us may well appear indefinite may easily be conceived to pass without a single instance of collision, in the nature of a catastrophe. Such may have gradually become rarer as the system has emerged from what must be considered its chaotic state, till at length, in the fulness of time, and, under the pre-arranging guidance of that DESIGN which pervades universal nature, each individual may have taken up such a course as to annul the possibility of further destructive interference."

To which we may add, that it is well understood, that, with respect to *all* this, Sir J. Herschel has but fully and clearly expressed the very thoughts and feelings of his distinguished father.

[The supposed "aggregation," in view of what is stated in *Note (A)*, must be regarded as being a wider segregation, by the continuance of an even now progressive *dispersion*.]

In so far as the *nebular hypothesis* here under consideration, has, at least, the character of an ingenious conjecture in the form of a generalization, it would seem to relate to a more ancient state of things than that contemplated in our *Note (A)*; being indicative of the way in which the rotating spheroids there described *might* themselves have been formed.

The existing phenomena seem to *require* the spheroids to have preceded the present state of things; but there is very little to indicate what must have been the state of the material composing the spheroids before *they* acquired their form.

The revelations by the spectroscope of a similarity of molecular constitution in so very many instances are not indeed inconsistent with the supposition of a common origin; yet *they* do not *require* that.

The statement of Sir J. Herschel, already quoted, speaks of the "chain of causes

and effects" here in question as being antecedent to the existence of self-luminous solid bodies.

Being thus antecedent, the traces of the phenomena which have *required* the admission of such causes and effects have, it would seem, been so far obliterated, in the course of the changes which have since taken place, that the nebular hypothesis here in question cannot now be proved; and yet enough has even here been stated, to show that it cannot be disproved.

THE following Memoir, on the "General Integrals of Planetary Motion," was submitted to Prof. H. A. Newton, of Yale College, and Mr. G. W. Hill, of Nyack, N. Y., and has received their approval for publication in the "Smithsonian Contributions to Knowledge."

JOSEPH HENRY,  
*Secretary Smithsonian Institution.*

WASHINGTON, D. C.,  
December, 1874.

## P R E F A C E.

---

THE present memoir may be considered as, in part, an extension and generalization of two former papers by the author: the first being *Théorie des perturbations de la Lune qui sont dues à l'action des Planètes*, published in *Liouville's Journal*, tome xvi., 1871; and the second, *Sur un Théorème de Mécanique Céleste*, published in the *Comptes Rendus*, tome lxxv. Notwithstanding its extent, the author is conscious, in his treatment of the subject, of several gaps, which may detract from entire rigor. He believes that some of these are of such a nature that the reader can readily fill them, while the remainder would have led into long digressions, and thus caused great delay in the publication of the paper. To the former class belong (1) the analogy between the expressions for the rectangular co-ordinates  $x$  and  $y$ , which differ only in that the latter is composed of products of sines, while the former is composed of similar products of cosines; and (2) the omission of all considerations of the modifications growing out of the fact that in equation (1) one value of  $h$  vanishes. To the latter class belong the omission of all considerations respecting the convergence of the series encountered, respecting terms of long period, and respecting the occurrence of relations among the arguments, such as that known to subsist between the mean motions of three of the satellites of Jupiter. These subjects will naturally come up for consideration when the process of actually integrating the differential equations of planetary motion in the most general way is undertaken. No method for the actual execution of this integration is given at present, partly because the paper may be considered complete without it, partly because the author has not succeeded in working out any method satisfactory to himself. It is true that a large part of the paper is devoted to reviewing the general forms met with in a certain integrating process, but the actual execution of this process, even for a single approximation, may be considered impracticable on account of the enormous labor involved in it. It is shown, by a bird's eye view, that a certain object is, in the nature of things, attainable; but a practicable way of actually reaching it is yet to be pointed out. It would be extremely agreeable to the author to learn that abler hands than his were successfully working to effect the actual solution of this noble problem in its most general form.

ON THE  
GENERAL INTEGRALS OF PLANETARY MOTION.

---

§ 1. *Introduction.*

IF we examine what has been done by geometers towards developing the coordinates of the planets in terms of the time, we shall see that the most general expressions yet found are those for the development of the secular variations of the elements in a periodic form. It is well known that if we neglect quantities of the third order with respect to the eccentricities and inclinations, the integration of the equations which give the secular variations of those elements, and of the longitudes of the perihelia and of the nodes, leads to the conclusion that the general expressions of those elements in terms of the time are of the form

$$\begin{aligned} e \sin \pi &= \sum_1^n N_i \sin (g_i t + \beta_i) \\ e \cos \pi &= \sum_1^n N_i \cos (g_i t + \beta_i) \\ \varphi \sin \theta &= \sum_1^n M_i \sin (h_i t + \gamma_i) \\ \varphi \cos \theta &= \sum_1^n M_i \cos (h_i t + \gamma_i) \end{aligned} \tag{1}$$

$n$  being the number of planets,  $N_i$ ,  $M_i$ ,  $g_i$ , and  $h_i$  being functions of the eccentricities at a given epoch and of the mean distances, while  $\beta_i$  and  $\gamma_i$  are angles depending also on the positions of the perihelia and nodes at a given epoch. It is to be remarked that one of the values of  $h_i$  is zero, the corresponding quantities  $M$  and  $\gamma$  depending on the position of the plane of reference.

The numerical values of these constants for the solar system have been found by several geometers. The latest and most complete determinations are those of Le Verrier and of Stockwell.<sup>1</sup>

When we consider the terms commonly called periodic, that is, those which depend on the mean longitudes of the planets, we shall find that their determination depends on the integration of differentials of the form

$$m' h \frac{\cos}{\sin} (i' \ell + i \ell + j' \pi' + j \pi + k' \theta' + k \theta),$$

where we put  
 $m'$  the mass of the disturbing planet.

---

<sup>1</sup> Smithsonian Contributions to Knowledge, No. 232. Vol. XVIII.  
1 October, 1874.

$h$  a function of the eccentricities, inclinations, and mean distances of the two planets, developable in powers of the two former quantities.

$l, l'$  the mean longitudes of the planets.

$\pi, \pi'$  the longitudes of their perihelia.

$\theta, \theta'$  the longitudes of their nodes.

$i, j, k$ , numerical integer coefficients,

and in which  $i' + i + j' + j + k' + k = 0$ .

The coefficient  $h$  is of the form

$$Ae^{i\theta^j}\phi^k\phi'^{k'}(1 + A_1e^2 + A_2e^2 + \text{etc.}),$$

while the circular function of which it is a coefficient may be put in the form

$$\begin{aligned} & \frac{\cos}{\sin}(j\pi + j'\pi' + k\theta + k'\theta') \cos(i'l + il) \\ & \pm \frac{\sin}{\cos}(j\pi + j'\pi' + k\theta + k'\theta') \sin(i'l + il). \end{aligned}$$

As these equations have hitherto been integrated the different elements are developed in powers of the time, and we are thus led to expressions of the form

$$(A + A't + A''t^2 + \dots) \frac{\cos}{\sin}(i'l + il).$$

But it is clear, that we shall get more general expressions if, instead of using developments in powers of the time, we substitute the general values of the elements given by equations (1). The substitution will be most readily made by reducing the circular to exponential functions. Putting in (1) for brevity

$$g_i t + \beta_i = \lambda_i$$

$$h_i t + \gamma_i = \lambda'_i$$

and

$$\Pi = \varepsilon^{\pi\sqrt{-1}}$$

$$\Lambda = \varepsilon^{\lambda\sqrt{-1}}$$

$$\Theta = \varepsilon^{\theta\sqrt{-1}},$$

the equations (1) may be put in the form

$$\begin{aligned} e\Pi &= \sum_i N_i \Lambda_i \\ e\Pi^{-1} &= \sum_i N_i \Lambda_i^{-1} \\ \phi\Theta &= \sum_i M_i \Lambda_i \\ \phi\Theta^{-1} &= \sum_i M_i \Lambda_i^{-1}. \end{aligned}$$

In the preceding differential to be integrated the coefficient of  $\frac{\sin}{\cos}(i'l + il)$  is of the form

$$(1 + A_1e^2 + A_2e^2 + \text{etc.}) Ae^{i\theta^j}\phi^k\phi'^{k'} \frac{\cos}{\sin}(j\pi + j'\pi' + k\theta + k'\theta').$$

If in the last factor we substitute the preceding exponentials for the circular functions, its product by  $e^{j\theta^j}\phi^k\phi'^{k'}$  in the case of a cosine reduces to half of the sum

$$(e\Pi)^j (e\Pi')^{j'} (\phi\Theta)^k (\phi'\Theta)^{k'} + \left(\frac{e}{\Pi}\right)^j \left(\frac{e'}{\Pi'}\right)^{j'} \left(\frac{\phi}{\Theta}\right)^k \left(\frac{\phi'}{\Theta'}\right)^{k'}.$$

Substituting the values of these expressions in terms of the exponentials just given, developing by the polynomial theorem, and then substituting for the expo-

nentials their expressions in circular functions, we find that this sum reduces to a series of terms, each of the form

$$h \frac{\cos}{\sin} (i_1 \lambda_1 + i_2 \lambda_2 + \dots + i_n \lambda_n + j_1 \lambda'_1 + j_2 \lambda'_2 + \dots + j_n \lambda'_n),$$

in each of which we have

$$\begin{aligned} i_1 + i_2 + \dots + i_n &= j + j' \\ j_1 + j_2 + \dots + j_n &= k + k'. \end{aligned}$$

The expressions  $A_1 e^2 + A_2 e'^2 + \text{etc.}$ , comprising products and powers of the squares of  $e, e', \phi$  and  $\phi'$  by constant coefficients by the substitutions of the values (1) reduce themselves to a series of terms of the form

$$h \cos (i_1 \lambda_1 + i_2 \lambda_2 + \dots + i_n \lambda_n + \dots + j_1 \lambda'_1 + j_2 \lambda'_2 + \dots + j_n \lambda'_n),$$

in which

$$i_1 + i_2 + \dots + j_1 + j_2 + \dots = 0.$$

By these operations and by corresponding ones in the case of sines the expressions to be integrated finally reduce themselves to the form

$$m' A' \frac{\sin}{\cos} (i'l + i'l + i_1 \lambda_1 + i_2 \lambda_2 + \dots + j_1 \lambda'_1 + \dots + j_n \lambda'_n),$$

in each of which the sum of the integral coefficients of the variable angles vanishes, while  $A'$  is a function of the mean distances and of the  $2n$  quantities  $N_i$  and  $M_i$ . By integration this expression will remain of the same form, so that we may regard it as a general form for the perturbation due to the mutual action of two planets, the elements of each being corrected for secular variations. If we consider the action of all the planets in succession, we shall introduce no new variable angles except their mean longitudes, which will make  $n$  mean longitudes in all. We shall therefore have, at the utmost, not more than  $3n$  variable angles.

We may thus conclude inductively that by the ordinary methods of approximation, the co-ordinates of each of  $3n$  planets, moving around the sun in nearly circular orbits, and subjected to their mutual attractions, may be expressed by an infinite series of terms each of the form

$$k \frac{\cos}{\sin} (i_1 \lambda_1 + i_2 \lambda_2 + \dots + i_{3n} \lambda_{3n}) \quad (2)$$

$i_1, i_2 \dots i_{3n}$  being integer coefficients, different in each term;  $\lambda_1, \lambda_2 \dots \lambda_{3n}$  being each of the form

$$l_i + b_i t$$

$l_1, l_2 \dots l_{3n}$  being  $3n$  arbitrary constants, and  $b_1, b_2 \dots b_{3n} k$ , being functions of  $3n$  other arbitrary constants.

We shall further assume that the inclination of the orbit of each planet to the plane of  $xy$  is so small that the co-ordinates may be developed in a convergent series, arranged according to the powers of this inclination, while it may be shown that the general expressions for the rectangular co-ordinates will be of the form

$$\begin{aligned} x &= Sk \cos (i_1 \lambda_1 + i_2 \lambda_2 + \dots + i_{3n} \lambda_{3n}) \\ y &= Sk \sin (i_1 \lambda_1 + i_2 \lambda_2 + \dots + i_{3n} \lambda_{3n}) \\ z &= Sc \sin (j_1 \lambda_1 + j_2 \lambda_2 + \dots + j_{3n} \lambda_{3n}) \end{aligned} \quad (3)$$

The letter  $S$  being used to express the sum of an infinite series of similar terms;  $k$ ,  $i$ , and  $j$  having the signification just expressed, and each system of values of the integers  $i$  and  $j$  being subjected to the condition

$$\begin{aligned} i_1 + i_2 + i_3 + \dots + i_{3n} &= 1 \\ j_1 + j_2 + j_3 + \dots + j_{3n} &= 0 \end{aligned} \quad (3)'$$

It is evident that when  $x$ ,  $y$ , and  $z$  are expressed in this form, any entire function of these quantities will reduce itself to the same form.

We shall now proceed to show that the form (3) is a general one: that is to say, that having an approximate solution of this form, if we make further approximations, developed in powers of the errors of this first solution, every approximation can be expressed in the form (3).

We can make no general determination of the limits within which these approximations will be convergent, we are therefore obliged to assume their convergency.

### § 2. Canonical Transformation of the Equations of Motion.

If we put

$\Omega$ , the potential of the  $n + 1$  bodies, that is, the sum of the products of every pair of masses divided by their mutual distance, the differential equations of motion will be  $3(n + 1)$  in number, each of the form

$$m_i \frac{d^2 x_i}{dt^2} = \frac{\partial \Omega}{\partial x_i}.$$

If we substitute for the co-ordinates themselves their products by the square roots of their masses, putting

$$X_i = m_i^{\frac{1}{2}} x_i; \quad Y_i = m_i^{\frac{1}{2}} y_i, \text{ etc.,}$$

the differential equations will assume the canonical form

$$\frac{d^2 X_i}{dt^2} = \frac{\partial \Omega}{\partial X_i}. \quad (4)$$

We suppose the index  $i$  to assume for each of the three co-ordinates all values from 0 to  $n$ , the value 0 referring to the sun, and we thus have  $3(n + 1)$  equations of the form (4) the integration of which will give the co-ordinates in terms of the time, and  $6(n + 1)$  arbitrary constants.

We shall now diminish the number of variables to be determined in the following general manner: Suppose that we have  $m$  differential equations of the first order, between  $m$  variables and the time  $t$ , each being of the form

$$\frac{dx_i}{dt} = X_i.$$

Suppose also that we have found  $k$  integrals of these equations, each of the form

$$f(x_1, x_2, \dots, x_m, t) = \text{constant}.$$

Let us assume at pleasure  $m - k$  other independent functions of the variables, each of the form

$$\xi_i = \phi_i(x_1, x_2, \dots, x_m, t),$$

so that the  $m$  variables  $x$  can be expressed as a function of  $k$  arbitrary constants, the time  $t$ , and the  $m-k$  variables

$$\xi_1, \xi_2, \dots, \xi_{m-k}$$

Differentiating the above expression for  $\xi_i$ , and substituting for  $\frac{dx}{dt}$  its value  $X$ , we shall have

$$\frac{d\xi_i}{dt} = \frac{\partial \phi_i}{\partial t} + X_1 \frac{\partial \phi_i}{\partial x_1} + X_2 \frac{\partial \phi_i}{\partial x_2} + \dots + X_m \frac{\partial \phi_i}{\partial x_m}$$

By substituting for the  $x$ 's in the right hand side of this equation their expressions in terms of  $\xi_1, \dots, \xi_{m-k}, t$ , and the arbitrary constants, we shall have the problem reduced to the integration of  $m-k$  equations between that number of variables.

In the special problem now under consideration, the  $m$  variables are the co-ordinates  $x, y, z$ , and their first derivatives with respect to the time. The integrals by which we shall seek to reduce the number of the variables are those of the conservation of the centre of gravity. We shall take for  $\xi_1, \xi_2$ , etc., linear functions of  $x_1, x_2$ , etc., so chosen that the reduced equations shall maintain the canonical form. Let us take the  $n+1$  linear functions of the co-ordinates  $x$ :—

$$\begin{aligned} \xi_0 &= a + bt = \alpha_{00}x_0 + \alpha_{01}x_1 + \dots + \alpha_{0n}x_n \\ \xi_1 &= \alpha_{10}x_0 + \alpha_{11}x_1 + \dots + \alpha_{1n}x_n \\ &\vdots \qquad \qquad \qquad \vdots \qquad \qquad \qquad \vdots \\ \xi_n &= \alpha_{n0}x_0 + \alpha_{n1}x_1 + \dots + \alpha_{nn}x_n \end{aligned} \quad (5)$$

where we have put for symmetry

$$m_i = c\alpha_{0i}, \text{ or } \alpha_{0i} = \frac{m_i}{c}, \quad (6)$$

$c$  being an arbitrary coefficient, while the other coefficients are to be chosen, so that the resulting differential equations shall be of the canonical form. Let us represent the values of  $x$  which we obtain from these equations by

$$x_i = \beta_{0i}\xi_0 + \beta_{1i}\xi_1 + \beta_{2i}\xi_2 + \dots + \beta_{ni}\xi_n. \quad (7)$$

Differentiating any one of the preceding expressions for  $\xi$ , and substituting for  $\frac{d^2x}{dt^2}$  its value, we have

$$\frac{\partial^2 \xi_i}{dt^2} = \frac{\alpha_{i0}}{m_0} \frac{\partial \Omega}{\partial x_0} + \frac{\alpha_{i1}}{m_1} \frac{\partial \Omega}{\partial x_1} + \dots + \frac{\alpha_{in}}{m_n} \frac{\partial \Omega}{\partial x_n}$$

If we suppose  $x_0, x_1$ , etc., replaced by their expressions in  $\xi_0, \xi_1$ , etc., obtained by solving the equations (5), that is, by their values in (7), we shall have

$$\frac{\partial \Omega}{\partial x_j} = \alpha_{0j} \frac{\partial \Omega}{\partial \xi_0} + \alpha_{1j} \frac{\partial \Omega}{\partial \xi_1} + \dots + \alpha_{nj} \frac{\partial \Omega}{\partial \xi_n}$$

Substituting these values in the preceding equation, it becomes

$$\begin{aligned} \frac{d^2 \xi_i}{dt^2} = & \left( \frac{\alpha_{00} \alpha_{i0}}{m_0} + \frac{\alpha_{01} \alpha_{i1}}{m_1} + \frac{\alpha_{02} \alpha_{i2}}{m_2} + \dots + \frac{\alpha_{0n} \alpha_{in}}{m_n} \right) \frac{\partial \Omega}{\partial \xi_0} \\ & + \left( \frac{\alpha_{10} \alpha_{i0}}{m_0} + \frac{\alpha_{11} \alpha_{i1}}{m_1} + \frac{\alpha_{12} \alpha_{i2}}{m_2} + \dots + \frac{\alpha_{1n} \alpha_{in}}{m_n} \right) \frac{\partial \Omega}{\partial \xi_1} \\ & \vdots \\ & + \left( \frac{\alpha_{n0} \alpha_{i0}}{m_0} + \frac{\alpha_{n1} \alpha_{i1}}{m_1} + \frac{\alpha_{n2} \alpha_{i2}}{m_2} + \dots + \frac{\alpha_{nn} \alpha_{in}}{m_n} \right) \frac{\partial \Omega}{\partial \xi_n}. \end{aligned}$$

In order that this equation may reduce to the canonical form

$$\frac{d^2 \xi_i}{dt^2} = \frac{\partial \Omega}{\partial \xi_i},$$

it is necessary and sufficient that the expressions

$$\frac{\alpha_{j0} \alpha_{i0}}{m_0} + \frac{\alpha_{j1} \alpha_{i1}}{m_1} + \frac{\alpha_{j2} \alpha_{i2}}{m_2} + \dots + \frac{\alpha_{jn} \alpha_{in}}{m_n}$$

should vanish whenever  $i$  is different from  $j$ , and should reduce to unity whenever  $i=j$ . In other words, it is necessary and sufficient that the coefficients  $\alpha$  should be so chosen that the  $(n+1)^2$  quantities

$$\begin{array}{ccccccc} \frac{\alpha_{00}}{\sqrt{m_0}}, & \frac{\alpha_{01}}{\sqrt{m_1}}, & \dots & \dots & \dots & \dots & \frac{\alpha_{0n}}{\sqrt{m_n}} \\ \vdots & \vdots & & & & & \vdots \\ \frac{\alpha_{n0}}{\sqrt{m_0}}, & \frac{\alpha_{n1}}{\sqrt{m_1}}, & \dots & \dots & \dots & \dots & \frac{\alpha_{nn}}{\sqrt{m_n}} \end{array} \quad (8)$$

should form an orthogonal system. The first line of coefficients is already determined by the equation (6), the coefficient  $c$  excepted, which is to be determined by the condition

$$\frac{\alpha_{00}^2}{m_0} + \frac{\alpha_{01}^2}{m_1} + \dots + \frac{\alpha_{0n}^2}{m_n} = 1,$$

or, from (6)

$$m_0 + m_1 + \dots + m_n = c^2,$$

which gives

$$c = \sqrt{m},$$

putting  $m$  for the sum of the masses of the entire system of bodies. Having thus

$$\alpha_{0i} = \frac{m_i}{\sqrt{m}},$$

the orthogonal system (8) becomes

$$\begin{array}{ccccccc} \frac{\sqrt{m_0}}{\sqrt{m}}, & \frac{\sqrt{m_1}}{\sqrt{m}}, & \dots & \dots & \dots & \dots & \frac{\sqrt{m_n}}{\sqrt{m}} \\ \frac{\alpha_{10}}{\sqrt{m_0}}, & \frac{\alpha_{11}}{\sqrt{m_1}}, & \dots & \dots & \dots & \dots & \frac{\alpha_{1n}}{\sqrt{m_n}} \\ \vdots & \vdots & & & & & \vdots \\ \frac{\alpha_{n0}}{\sqrt{m_0}}, & \frac{\alpha_{n1}}{\sqrt{m_1}}, & \dots & \dots & \dots & \dots & \frac{\alpha_{nn}}{\sqrt{m_n}} \end{array}$$

The number of coefficients to be determined is now  $n(n+1)$ . The total number of conditions which the system must satisfy is  $\frac{(n+1)(n+2)}{2}$ , but one of these being already satisfied by the quantities in the first line, there remain only  $\frac{n(n+3)}{2}$  conditions to be satisfied by  $n(n+1)$  quantities, we have therefore

$$n(n+1) - \frac{n(n+3)}{2} = \frac{n(n-1)}{2}$$

quantities which may be chosen at pleasure.

The general theory of the substitution which we have been considering, and the various modes in which the orthogonal system just found may be formed, have been developed very fully by Radau in a paper in *Annales de l'Ecole Normale Supérieure*, Tome V. (1868).<sup>1</sup> We shall, therefore, at present confine ourselves to a brief indication of the special form of the substitution which has been found useful in Celestial Mechanics. We first remark that if we form the  $(n+1)$  equations

$$y_i = \frac{\alpha_{i0}}{\sqrt{m_0}} z_0 + \frac{\alpha_{i1}}{\sqrt{m_1}} z_1 + \dots + \frac{\alpha_{in}}{\sqrt{m_n}} z_n$$

by giving  $i$  in succession all values from 0 to  $n$ , we shall have by the theory of orthogonal substitutions the  $(n+1)$  equations

$$z_i = \frac{\alpha_{0i}}{\sqrt{m_i}} y_0 + \frac{\alpha_{1i}}{\sqrt{m_i}} y_1 + \dots + \frac{\alpha_{ni}}{\sqrt{m_i}} y_n.$$

If we suppose in the first equations

$$z_j = \sqrt{m_j} x_j$$

we shall have from (5)

$$y_i = \xi_{i0}$$

whence, by substituting these values of  $z_i$  and  $y_i$  in the second equation, we shall have for the expression of  $x_i$  in terms of  $\xi_0, \xi_1$ , etc. to replace equation (7)

$$x_i = \frac{1}{\sqrt{m}} \xi_0 + \frac{\alpha_{1i}}{m_i} \xi_1 + \frac{\alpha_{2i}}{m_i} \xi_2 + \text{etc.} \tag{9}$$

The first term of this expression is common to all the values of  $x_i$ , representing, as it does, the co-ordinates of the centre of gravity of the system. It may, therefore, be omitted entirely, when we seek only the relative co-ordinates of the various bodies, and, in any case, it will disappear from the differential equations of motion.

The most simple way of forming the coefficients  $\alpha_{ij}$  is to suppose  $\frac{n(n-1)}{2}$  of them equal to zero. Let us first suppose  $\alpha_{ij} = 0$  whenever  $j > i$ , the first line, in which  $i = 0$ , being, of course, excepted.

The orthogonal system will then be of the form

<sup>1</sup> Sur une Transformation des Equations Différentielles de la Dynamique.

$$\begin{array}{ccccccc}
 \frac{\sqrt{m_0}}{\sqrt{m}}, & \frac{\sqrt{m_1}}{\sqrt{m}}, & \frac{\sqrt{m_2}}{\sqrt{m}}, & \dots & \dots & \frac{\sqrt{m_n}}{\sqrt{m}} & \\
 \frac{\alpha_{10}}{\sqrt{m_0}}, & \frac{\alpha_{11}}{\sqrt{m_1}}, & 0, & 0, & \dots & 0 & (10) \\
 \frac{\alpha_{20}}{\sqrt{m_0}}, & \frac{\alpha_{21}}{\sqrt{m_1}}, & \frac{\alpha_{22}}{\sqrt{m_2}}, & 0, & \dots & 0 & \\
 \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \\
 \frac{\alpha_{n0}}{\sqrt{m_0}}, & \frac{\alpha_{n1}}{\sqrt{m_1}}, & \frac{\alpha_{n2}}{\sqrt{m_2}}, & \dots & \dots & \frac{\alpha_{nn}}{\sqrt{m_n}}. & 
 \end{array}$$

Then  $\alpha_{nn}$  will be determined by the condition

$$\frac{\alpha_{nn}^2}{m_n} + \frac{m_n}{m} = 1,$$

while all the other coefficients in the bottom line will be determined by the condition

$$\frac{\alpha_{ni} \alpha_{nn}}{\sqrt{m_i} m_n} + \frac{\sqrt{m_i m_n}}{m} = 0.$$

Taking the line next the bottom the diagonal coefficient will be determined by the equation

$$\frac{\alpha_{n, n-1}^2}{m_{n-1}} + \frac{\alpha_{n-1, n-1}^2}{m} + \frac{m_{n-1}}{m} = 1,$$

while the remaining coefficients of the form  $\alpha_{n-1, i}$  will be given by the equations

$$\frac{\alpha_{n, i} \alpha_{n, n-1} + \alpha_{n-1, i} \alpha_{n-1, n-1}}{\sqrt{m_i} m_{n-1}} + \frac{\sqrt{m_i m_{n-1}}}{m} = 0.$$

The general values of the coefficients to which we are thus led may be expressed in the following way: put

$$\mu_i = m_0 + m_1 + \dots + m_i$$

by which  $m$  will become  $\mu_n$ . Also, suppose

$$v_j = \frac{\sqrt{m_j}}{\sqrt{\mu_j \mu_{j-1}}}.$$

We shall then have

$$\alpha_{ii}^2 = \frac{m_i \mu_{i-1}}{\mu_i}$$

$$\alpha_{ji} = -v_j m_i \dots (i < j).$$

It is easy to prove that the coefficients thus formed fulfil the required conditions.

If we substitute these values of the coefficients in the expressions for  $\xi_1$  and  $\xi_2$ , they become

$$\xi_1 = \frac{\sqrt{m_0 m_1}}{\sqrt{m_0 + m_1}} (x_1 - x_0)$$

$$\xi_2 = \frac{\sqrt{m_2}}{\sqrt{\mu_1 \mu_2}} \left( (m_0 + m_1) x_2 - m_1 x_1 - m_0 x_0 \right).$$

We see that, supposing  $x_0$  to represent the co-ordinates of the sun or other central body,  $\xi_1$  is equal to the co-ordinate of the first planet, which may be any one at pleasure, relatively to the sun, multiplied by a function of the masses, while  $\xi_2$  is equal to the co-ordinate of the second planet relatively to the centre of gravity of the sun and first planet multiplied by another function of the masses, and so on. These functions  $\xi_i$ , when divided by the functions of the masses just alluded to, will differ from the co-ordinates of the several planets relatively to the sun only by quantities of the order of magnitude of the masses of the planets divided by that of the sun.

In what precedes we have considered only the co-ordinates  $x_1$ . Of course the other co-ordinates are to be subjected to the same transformation. If we represent by  $\eta$  and  $\zeta$  the corresponding functions of  $y$  and  $z$ , and if in the expressions for  $\xi$ ,  $\eta$ , and  $\zeta$  we substitute for  $x$ ,  $y$ , and  $z$ , the expressions (3), those quantities will themselves reduce to expressions of this same form.

§ 3. *Approximation to the Required Solutions by the Variations of the Arbitrary Constants in a First Approximate Solution.*

By the transformation in question we have for the determination of the relative motion of the  $n + 1$  bodies,  $3n$  differential equations, of the canonical form

$$\frac{d^2 \xi_i}{dt^2} = \frac{\partial \Omega}{\partial \xi_i}; \quad \frac{d^2 \eta_i}{dt^2} = \frac{\partial \Omega}{\partial \eta_i}; \quad \frac{d^2 \zeta_i}{dt^2} = \frac{\partial \Omega}{\partial \zeta_i}. \quad (11)$$

Let us now suppose that we have found approximate solutions of these equations in the form (3), the quantities  $x$ ,  $y$ ,  $z$  being there replaced by  $\xi_i$ ,  $\eta_i$  and  $\zeta_i$ , that is, solutions which possess the property that, if, on the one hand, each expression is twice differentiated, and if, on the other hand, the values (3) are substituted in the second members of (11), the two expressions shall differ only by terms multiplied by small numerical coefficients. We have to show that when we make a further approximation to quantities of the first order relative to these coefficients, the solution will still admit of being expressed in the form (3). To do this we shall make the further approximation by the method of the variation of arbitrary constants, remarking, however, that the usual formulæ of this method cannot be applied, because they presuppose that the first approximation is a *rigorous* solution of an approximate dynamical problem, while, in the present case, we are not entitled to assume that our approximate solution (3) possesses this quality; in other words, we are not entitled to assume that any function  $\Omega_0$  of the quantities  $\xi$ ,  $\eta$ , and  $\zeta$ , can be formed, such that we shall find the  $3n$  equations of the form

$$\frac{d^2 \xi_i}{dt^2} = \frac{\partial \Omega_0}{\partial \xi_i}$$

rigorously and identically satisfied by the approximate expressions, both with respect to the time, and the  $6n$  constants which the solution contains. Consequently, we cannot assume the existence of a perturbative function, and must employ other expressions in place of the derivatives of that function.

We set out, then, with the three sets of equations, having  $n$  in each set

$$\begin{aligned} \xi_i &= Sk_i \cos (i_1\lambda_1 + i_2\lambda_2 + \dots + i_{3n}\lambda_{3n}) \\ \eta_i &= Sk_i \sin (i_1\lambda_1 + i_2\lambda_2 + \dots + i_{3n}\lambda_{3n}) \\ \zeta_i &= Sk'_i \sin (j_1\lambda_1 + j_2\lambda_2 + \dots + j_{3n}\lambda_{3n}), \end{aligned} \tag{12}$$

in which all the quantities are supposed to be given in terms of  $6n$  arbitrary constants and the time, each  $\lambda$  being of the form

$$\lambda_i = l_i + b_i t,$$

$l_i$  being an arbitrary constant, which each  $b$ ,  $k$ , and  $k'$  is given as a function of  $3n$  other arbitrary constants, which we may represent in the most general way by

$$a_1, a_2, \dots, a_{3n}.$$

So long as no distinction between  $a$  and  $l$  is necessary, we may represent the entire  $6n$  arbitrary constants by

$$a_1, a_2, \dots, a_{6n},$$

Let us now take the complete second derivatives of (12) with respect to the time, supposing all  $6n$  constants variable. We shall suppose the variable constants to fulfil Lagrange's conditions, now  $3n$  in number:—

$$\sum_{j=1}^{j=6n} \frac{\partial \xi_i}{\partial a_j} \frac{da_j}{dt} = 0; \quad \sum_{j=1}^{j=6n} \frac{\partial \eta_i}{\partial a_j} \frac{da_j}{dt} = 0; \quad \sum_{j=1}^{j=6n} \frac{\partial \zeta_i}{\partial a_j} \frac{da_j}{dt} = 0, \tag{13}$$

which will give

$$\frac{d\xi_i}{dt} = \frac{\partial \xi_i}{\partial t} = \xi'_i, \text{ etc.}$$

From the second derivatives, combined with the differential equations (11), we shall have  $3n$  equations of the form

$$\sum_{j=1}^{j=6n} \frac{\partial \xi'_i}{\partial a_j} \frac{da_j}{dt} = \frac{\partial \Omega}{\partial \xi_i} - \frac{\partial^2 \xi_i}{\partial t^2},$$

which it is required to satisfy. The expression in the right-hand member of this equation corresponds to  $\frac{\partial R}{\partial \xi_i}$  in the usual theory, when  $R$  is the perturbative function.

Let us multiply this equation by  $\frac{d\xi_i}{da_k}$ , and add up the  $3n$  equations which we may form in this way by substituting for  $\xi_i$  all the values of  $\xi$ ,  $\eta$ , and  $\zeta$  in succession. We may thus obtain

$$\sum_{i=1}^{i=n} \sum_{j=1}^{j=6n} \frac{\partial \xi'_i}{\partial a_k} \frac{\partial \xi'_i}{\partial a_j} \frac{da_j}{dt} = \frac{\partial \Omega}{\partial a_k} - \sum_{i=1}^{i=n} \frac{\partial^2 \xi_i}{\partial t^2} \frac{\partial \xi_i}{\partial a_k},$$

the sign  $\Sigma'$  indicating that all values of  $\eta$  and  $\zeta$  as well as of  $\xi$  are to be included. The right-hand member of this equation corresponds to  $\frac{\partial R}{\partial a_k}$  in the usual theory.

Let us now multiply the equations (13), the first by  $\frac{\partial \xi'_i}{\partial a_k}$ , the second by  $\frac{\partial \eta'_i}{\partial a_k}$ , and the third by  $\frac{\partial \zeta'_i}{\partial a_k}$ , and add together the  $3n$  equations which may be thus formed by giving  $i$  all its values. If we subtract their sum from the last equation, putting

$$(a_n, a_j) = \sum_{i=1}^{i=n} \left( \frac{\partial \zeta_i}{\partial a_k} \frac{\partial \zeta'_i}{\partial a_j} - \frac{\partial \zeta_i}{\partial a_j} \frac{\partial \zeta'_i}{\partial a_k} \right), \tag{14}$$

we shall have

$$(a_k, a_1) \frac{da_1}{dt} + (a_k, a_2) \frac{da_2}{dt} + \dots \dots \text{etc.} = \frac{\partial \Omega}{\partial a_k} - \sum_{i=1}^{i=n} \frac{\partial^2 \zeta_i}{\partial t^2} \frac{\partial \zeta_i}{\partial a_k}, \tag{15}$$

the sign  $\Sigma'$  including, as before, not only all values of  $i$  from 1 to  $n$ , but the corresponding terms in  $\eta$  and  $\zeta$ .

By giving  $k$  all values in succession from 1 to  $6n$ , we shall have a system of  $6n$  differential equations, the integration of which will give the values of the  $6n$  quantities

$$a_1, a_2, \dots \dots a_{6n}$$

in terms of the time.

By the fundamental assumption with which we set out, the expressions for  $\xi$ ,  $\eta$ , and  $\zeta$  are such that the right hand members of these equations are small quantities of which we neglect the powers and products. We may, therefore, after solving these equations so as to get the derivatives in the form

$$\frac{da_i}{dt} = f(a_1, a_2, \dots \dots a_{6n}, t),$$

integrate by a simple quadrature, supposing  $a_1, a_2$ , etc., in the second members to be constant. Moreover we shall require the values of the quantities  $(a_k, a_j)$  only to the first degree of approximation, and within this limit they must necessarily conform to the well-known law of Lagrange of being functions of the constants only, and not containing the time explicitly. This theorem will materially assist us in their formation.

§ 4. *Formation of the Lagrangian Coefficients  $(a_i, a_k)$ , and Reduction of the Equations to a Canonical Form.*

Restoring the two classes of constants represented by  $a$  and  $l$ , we shall have three classes of the functions sought, included in the forms

$$(a_k, a_j), (l_k, l_j) \text{ and } (a_k, l_j).$$

Let us now differentiate the equations (12) with respect to the time, putting for brevity

$$\begin{aligned} i_1 b_1 + i_2 b_2 + \dots \dots + i_{3n} b_{3n} &= b \\ i_1 \lambda_1 + i_2 \lambda_2 + \dots \dots + i_{3n} \lambda_{3n} &= N \\ j_1 b_1 + j_2 b_2 + \dots \dots + j_{3n} b_{3n} &= b' \\ j_1 \lambda_1 + j_2 \lambda_2 + \dots \dots + j_{3n} \lambda_{3n} &= N'; \end{aligned}$$

we shall then have, omitting the index  $i$  of  $b, k$ , and  $N$ ,

$$\begin{aligned} \xi'_i &= -S b k \sin N \\ \eta'_i &= S b k \cos N \\ \zeta'_i &= S b' k' \cos N'. \end{aligned} \tag{15'}$$

To form the combination  $(a_k, a_j)$  we must differentiate the equations (12) and (15) with respect to  $a_i$  and  $a_n$ , and substitute the results in (14). In forming these quantities, two series of terms represented by the sign  $S$  of summation are to be

multiplied together, which renders it necessary to be more explicit in representing the double summation we thus encounter. Having  $n$  of each of the quantities  $\xi$ ,  $\eta$ , and  $\zeta$  distinguished by writing the various values of the index  $i$ , which takes all integer values from 1 to  $n$ , the quantities  $b$ ,  $k$ , and  $N$  should all be affected with this same index. But it is not necessary to write it after  $N$  or  $b$ , because each  $N$  is common to all the  $\xi$ 's and  $\eta$ 's, or to all the  $\zeta$ 's, respectively. Again, we have as many values of  $N$  as there are combinations of the coefficients  $i_1, i_2, i_3$ , etc., which enter into it, while each  $N$  has its corresponding coefficients  $k, i$  in number. We must, therefore, consider  $k$  to be written

$$k_i(i_1, i_2, i_3 \dots \dots i_{3n}),$$

while  $b$  and  $N$  are affected with the same indices, the first excepted. In other words, we have

$$b(i_1, i_2, i_3 \dots \dots i_{3n}) = i_1 b_1 + i_2 b_2 + \dots \dots + i_{3n} b_{3n}$$

$$N(i_1, i_2, i_3 \dots \dots i_{3n}) = i_1 \lambda_1 + i_2 \lambda_2 + \dots \dots + i_{3n} \lambda_{3n}.$$

Then, in the sense in which we have hitherto used the sign of summation  $S$  we have symbolically

$$S = \sum_{i_1=-\infty}^{i_1=\infty} \sum_{i_2=-\infty}^{i_2=\infty} \dots \dots \sum_{i_{3n}=-\infty}^{i_{3n}=\infty}$$

To avoid the complication of writing so many indices we shall represent any one combination, as  $(i_1, i_2, \dots \dots i_{3n})$  by the symbol  $\nu$ , and any other combination by  $\mu$ . We shall also put

$$S' = \sum_{i=1}^{i=n} S.$$

This summation includes all the terms in all the values of any one co-ordinate, as  $\xi$ ,  $\eta$ , or  $\zeta$ , respectively. A sign for a summation including all  $3n$  co-ordinates is not here necessary, as  $k$  and  $N$  are common to  $\xi$  and  $\eta$ , while the corresponding quantities for  $\zeta$ , being of a different form, must be written separately. We have, in fact, distinguished them by an accent.

The co-ordinates and their derivatives which enter into the expressions  $(a_k, a_j)$  will then assume the following form, the index  $i$  being understood after  $k$  and  $k'$ .

$$\begin{aligned} \xi_i &= S_\nu k_\mu \cos N'_\mu \\ \eta_i &= S_\nu k_\mu \sin N'_\mu \\ \zeta_i &= S_\nu k'_\mu \sin N'_\mu \\ \xi'_i &= -S_\nu (bk)_\nu \sin N'_\nu \\ \eta'_i &= S_\nu (bk)_\nu \cos N'_\nu \\ \zeta'_i &= S_\nu (b'k')_\nu \cos N'_\nu \end{aligned} \quad (16)$$

$$\left. \begin{aligned} \frac{\partial \xi_i}{\partial a_k} &= S_\mu \left\{ \frac{\partial k_\mu}{\partial a_k} \cos N'_\mu - k_\mu \frac{\partial b_\mu}{\partial a_k} t \sin N'_\mu \right\} \\ \frac{\partial \eta_i}{\partial a_k} &= S_\mu \left\{ \frac{\partial k_\mu}{\partial a_k} \sin N'_\mu + k_\mu \frac{\partial b_\mu}{\partial a_k} t \cos N'_\mu \right\} \\ \frac{\partial \zeta_i}{\partial a_k} &= S_\mu \left\{ \frac{\partial k'_\mu}{\partial a_k} \sin N'_\mu + k'_\mu \frac{\partial b'_\mu}{\partial a_k} t \cos N'_\mu \right\} \end{aligned} \right\} \quad (17)$$

$$\left. \begin{aligned} \frac{\partial \xi'_i}{\partial a_j} &= S_r \left\{ -\frac{\partial(bk)_r}{\partial a_j} \sin N_r - (bk)_r \frac{\partial b}{\partial a_j} t \cos N_r \right\} \\ \frac{\partial \eta'_i}{\partial a_j} &= S_r \left\{ \frac{\partial(bk)_r}{\partial a_j} \cos N_r - (bk)_r \frac{\partial b}{\partial a_j} t \sin N_r \right\} \\ \frac{\partial \zeta'_i}{\partial a_j} &= S_r \left\{ \frac{\partial(b'k')_r}{\partial a_j} \cos N'_r - (b'k')_r \frac{\partial b'}{\partial a_j} t \sin N'_r \right\} \end{aligned} \right\} \quad (18)$$

By changing  $a_k$  into  $a_j$  in the three equations (17), and making the reverse change in (18), we have the complete expressions necessary to form any term of the expression

$$(a_k, a_j) = \sum_{i=1}^{i=n} \left\{ \frac{\partial \xi'_i}{\partial a_k} \frac{\partial \xi'_i}{\partial a_j} - \frac{\partial \xi'_i}{\partial a_j} \frac{\partial \xi'_i}{\partial a_k} + \frac{\partial \eta'_i}{\partial a_k} \frac{\partial \eta'_i}{\partial a_j} - \text{etc.} \right\}$$

We see at once that this expression will be of the form

$$\sum_{i=1}^{i=n} S_{\mu, \nu}^2 \left\{ A_{\mu, \nu} \sin(N_\mu - N_\nu) + A't + A''t^2 \right\}$$

Since the expression is known to be independent of  $t$ , we must have, to quantities of the first degree of approximation,  $A' = 0$  and  $A'' = 0$  by the condition that  $\xi$ ,  $\eta$ , and  $\zeta$  satisfy the original differential equations, and the coefficient  $A_{\mu, \nu}$  must vanish, unless we have

$$N_\mu - N_\nu = \text{constant.}$$

The coefficients  $b_1, b_2, \dots, b_{3n}$ , being supposed incommensurable, this can only happen when we have in (3')

$$i_{1\mu} = i_{1\nu}; \quad i_{2\mu} = i_{2\nu}, \text{ etc.},$$

and hence

$$N_\mu = N_\nu,$$

when  $\sin(N_\mu - N_\nu)$  will itself vanish. Hence,  $(a_k, a_j)$  containing no constant term whatever, we must have

$$(a_k, a_j) = 0. \quad (19)$$

Again, differentiating the equations (16), the first three with respect to  $l_k$  and the last three with respect to  $l_j$ , we find

$$\begin{aligned} \frac{\partial \xi'_i}{\partial l_k} &= -S_\mu (i_k k)_\mu \sin N_\mu \\ \frac{\partial \eta'_i}{\partial l_k} &= S_\mu (i_k k)_\mu \cos N_\mu \\ \frac{\partial \zeta'_i}{\partial l_k} &= S_\mu (j_k k)_\mu \cos N'_\mu \\ \frac{\partial \xi'_i}{\partial l_j} &= -S_r (i_j b k)_r \cos N_r \\ \frac{\partial \eta'_i}{\partial l_j} &= -S_r (i_j b k)_r \sin N_r \\ \frac{\partial \zeta'_i}{\partial l_j} &= -S_r (j_j b' k')_r \sin N'_r. \end{aligned}$$

From these expressions it may be shown that

$$(l_k, l_j) = 0 \tag{20}$$

in the same way that we found  $(a_k, a_j) = 0$ .

We have next to consider the combinations of the form  $(a_k, l_j)$ , for which the expression is

$$(a_k, l_j) = \sum_{i=1}^{i=n} \left\{ \frac{\partial \zeta_i}{\partial a_k} \frac{\partial \zeta_i'}{\partial l_j} - \frac{\partial \zeta_i}{\partial l_j} \frac{\partial \zeta_i'}{\partial a_k} + \frac{\partial \eta_i}{\partial a_k} \frac{\partial \eta_i'}{\partial l_j} - \text{etc.} \right\}$$

The terms which do not contain  $t$  as a factor are found to be

$$\begin{aligned} & - S_\mu S'_\nu \left\{ (i_j b k)_\nu \frac{\partial k'_\mu}{\partial a_k} + (i_j k)_\mu \frac{\partial (b k)_\nu}{\partial a_k} \right\} \cos(N'_\mu - N'_\nu) \\ & - \frac{1}{2} S_\mu S'_\nu \left\{ (j_j b' k')_\nu \frac{\partial k'_\mu}{\partial a_k} + (j_j k')_\mu \frac{\partial (b' k')_\nu}{\partial a_k} \right\} \cos(N''_\mu - N''_\nu). \end{aligned}$$

$S'$  having the meaning given on page 12.

The only non-periodic terms in this expression will be those in which  $\mu = \nu$ , and these terms reduce to

$$\begin{aligned} & - S' \left\{ i_j b k \frac{\partial k}{\partial a_k} + i_j k \frac{\partial (b k)}{\partial a_k} + \frac{1}{2} j_j b' k' \frac{\partial k'}{\partial a_k} + \frac{1}{2} j_j k' \frac{\partial (b' k')}{\partial a_k} \right\} \\ & = - S' \left\{ \frac{\partial (i_j b k^2)}{\partial a_k} + \frac{1}{2} \frac{\partial (j_j b' k'^2)}{\partial a_k} \right\} \end{aligned}$$

or, by putting

$$c_j = S' \left\{ i_j b k^2 + \frac{1}{2} j_j b' k'^2 \right\} \tag{21}$$

we have

$$(a_k, l_j) = - \frac{\partial c_j}{\partial a_k}. \tag{22}$$

These expressions are now to be substituted in the differential equations represented by (15), which will then divide into two classes according as the derivative of  $\Omega$  is taken with respect to  $l_1, l_2, \dots$  or  $l_{3n}$ , or with respect to  $a_1, a_2, \dots$  or  $a_{3n}$ . Having regard to equation (20) we find those of the first class to be of the form

$$(l_j, a_1) \frac{da_1}{dt} + (l_j, a_2) \frac{da_2}{dt} + \dots + (l_j, a_{3n}) \frac{da_{3n}}{dt} = \frac{\partial \Omega}{\partial l_j} - \sum_{i=1}^{i=n} \frac{\partial \zeta_i}{\partial t^2} \frac{\partial \zeta_i'}{\partial l_j}.$$

If, in the first member, we substitute for the coefficients their values (22), noticing that

$$(l_j, a_k) = -(a_k, l_j),$$

and in the second member put for brevity

$$\frac{\partial \Omega}{\partial l_j} - \sum_i \left\{ \frac{\partial^2 \zeta_i}{\partial t^2} \frac{\partial \zeta_i'}{\partial l_j} + \frac{\partial^2 \eta_i}{\partial t^2} \frac{\partial \eta_i'}{\partial l_j} + \frac{\partial^2 \zeta_i}{\partial t^2} \frac{\partial \zeta_i'}{\partial l_j} \right\} = \Omega_j,$$

the differential equation reduces to

$$\frac{\partial c_j}{\partial a_1} \frac{da_1}{dt} + \frac{\partial c_j}{\partial a_2} \frac{da_2}{dt} + \dots + \frac{\partial c_j}{\partial a_{3n}} \frac{da_{3n}}{dt} = \Omega_j,$$

or

$$\frac{dc_j}{dt} = \Omega_j. \tag{23}$$

By giving  $j$  all values in succession from 1 to  $3n$ , we shall have  $3n$  equations to determine the variations of  $c_1, c_2, \dots, c_{3n}$ , from which the variations of  $a_1, a_2, \dots, a_{3n}$  are to be obtained by the  $3n$  equations (21). But, for our present purposes, it will be more convenient to consider the  $c$ 's as the fundamental elements, and to consider  $a_1, a_2, \dots, a_{3n}$  to be replaced by  $c_1, c_2, \dots, c_{3n}$  in the original equations.

The second class of differential equations (15) will, by (19), be represented by

$$(a_k, l_1) \frac{dl_1}{dt} + (a_k, l_2) \frac{dl_2}{dt} + \text{etc.} = \frac{\partial \Omega}{\partial a_k} - \sum_{i=1}^{i=3n} \left\{ \frac{\partial^2 \zeta_i}{\partial t^2} \frac{\partial \zeta_i}{\partial a_k} + \frac{\partial^2 \eta_i}{\partial t^2} \frac{\partial \eta_i}{\partial a_k} + \frac{\partial^2 \zeta_i}{\partial t^2} \frac{\partial \zeta_i}{\partial a_k} \right\}$$

Substituting for the coefficients in the first member their values (23), we shall have  $3n$  equations represented by

$$\frac{\partial c_1}{\partial a_k} \frac{dl_1}{dt} + \frac{\partial c_2}{\partial a_k} \frac{dl_2}{dt} + \dots = - \frac{\partial \Omega}{\partial a_k} + \sum_{i=1}^{i=3n} \left\{ \frac{\partial^2 \zeta_i}{\partial t^2} \frac{\partial \zeta_i}{\partial a_k} + \text{etc.} \right\}$$

Putting  $k$  successively equal to 1, 2, . . . .  $3n$ , we shall have  $3n$  equations of this form. Let us multiply the first of these equations by  $\frac{\partial a_1}{\partial c_1}$ , the second by  $\frac{\partial a_2}{\partial c_1}$ , the  $i$ th by  $\frac{\partial a_i}{\partial c_1}$ , and so on to the  $3n$ th, and add all the products, noticing that the theory of functional determinants gives

$$\sum_{i=1}^{i=3n} \frac{\partial c_j}{\partial a_i} \frac{\partial a_i}{\partial c_k} = + 1 \text{ or } 0$$

according as  $k$  is or is not equal to  $j$ . Then, by putting

$$\frac{\partial \Omega}{\partial c_j} - \sum_{i=1}^{i=3n} \left\{ \frac{\partial^2 \zeta_i}{\partial t^2} \frac{\partial \zeta_i}{\partial c_j} + \frac{\partial^2 \eta_i}{\partial t^2} \frac{\partial \eta_i}{\partial c_j} + \frac{\partial^2 \zeta_i}{\partial t^2} \frac{\partial \zeta_i}{\partial c_j} \right\} = \Omega'_j,$$

we shall have

$$\begin{aligned} \frac{dl_1}{dt} &= - \Omega'_1 \\ \frac{dl_2}{dt} &= - \Omega'_2 \\ &\vdots \\ \frac{dl_{3n}}{dt} &= - \Omega'_{3n}. \end{aligned} \tag{24}$$

These  $3n$  equations, combined with the  $3n$  equations (23), will give, by simple integration by quadratures, the perturbation of the  $6n$  constants, which, being substituted in the original equations (12), will give values of the variables which satisfy the original differential equations to terms one order higher than they were satisfied by (12) originally.

It will be observed that if our functions of the time and  $6n$  arbitrary constants, which we have represented by  $\xi_i, \eta_i,$  and  $\zeta_i$ , possessed the property that a function  $\Omega_0$  of  $\xi, \eta,$  and  $\zeta$  could be found such that for all values of  $i$

$$\frac{\partial^2 \zeta_i}{\partial t^2} = \frac{\partial \Omega_0}{\partial \zeta_i}; \quad \frac{\partial^2 \eta_i}{\partial t^2} = \frac{\partial \Omega_0}{\partial \eta_i}; \quad \frac{\partial^2 \xi_i}{\partial t^2} = \frac{\partial \Omega_0}{\partial \xi_i}$$

we should have in (23) and (24) by putting  $R = \Omega - \Omega_0$ ,

$$\begin{aligned}\Omega_j &= \frac{\partial R}{\partial l_j} \\ \Omega'_j &= \frac{\partial R}{\partial c_j}\end{aligned}$$

§ 5. *Fundamental Relation between the Coefficients of the time,  $b_1, b_2, \text{etc.}$ , considered as Functions of  $c_1, c_2, \text{etc.}$*

In the preceding section we have found ourselves able to express the first approximate values of the variables in terms of  $3n$  pairs of arbitrary constants

$$\begin{array}{ccc} c_1 & l_1 \\ c_2 & l_2 \\ \vdots & \vdots \\ c_{3n} & l_{3n} \end{array}$$

in which the two members of each pair are *conjugate* to each other; or possess the property that the expressions (14) all vanish except when  $a_k$  and  $a_i$  represent the two members of a conjugate pair, in which case we have

$$(l_i, c_i) = +1. \quad (25)$$

The distinguishing characteristic of the integrals we have been investigating is that they do not contain the time, except as multiplied by the  $3n$  factors  $b$ , which are functions of the  $3n$  constants  $c$ . This characteristic will enable us to deduce a fundamental relation between the differential coefficients of  $b$  with respect to  $c$ . In the first place, we remark that each  $c$  has a  $b$  to which it stands in a peculiar relation, in that the latter, multiplied by the time, is added to the  $l$ , which is conjugate to  $c$  to form the corresponding  $\lambda$ . The theorem in question is this: each  $b$  being supposed to be marked with the index of its corresponding  $c$ , we shall have for all values of  $i$  and  $j$  from 1 to  $3n$ ,

$$\frac{\partial b_i}{\partial c_j} = \frac{\partial b_j}{\partial c_i};$$

in other words, the expression

$$\sum b_i dc_i$$

will be an exact differential.

It is quite possible that this theorem may admit of being deduced immediately from the preceding theory, but I have not succeeded in doing so, and have therefore been obliged to consider the problem in the reverse form. We have, in starting, supposed ourselves to have completely expressed the  $3n$  co-ordinates  $\xi, \eta, \zeta$ , as functions of the  $6n$  quantities

$$a_1, a_2, \dots, a_{3n}, \lambda_1, \lambda_2, \dots, \lambda_{3n},$$

and we have just shown how to replace the first  $3n$  quantities by the quantities  $c_1, c_2, \dots, c_{3n}$ . If we add to these the first derivatives of the co-ordinates (16)

we shall have  $6n$  variables, represented by  $\xi_i, \eta_i, \zeta_i, \xi'_i, \eta'_i, \zeta'_i$ , expressed as functions of the  $6n$  quantities

$$c_1, c_2, c_3 \dots c_{3n}, \lambda_1, \lambda_2, \lambda_3 \dots \lambda_{3n}$$

Let us now suppose these equations solved with respect to these last quantities. We shall then have  $6n$  equations of the form

$$c_i = \phi_i; \lambda_i = \Psi_i, \text{ whence } \bar{l}_i = \Psi_i - \bar{b}_i t, \tag{26}$$

$\phi$  and  $\Psi$  being functions of  $\xi, \eta, \zeta$ , etc. The first and third of these expressions are the  $6n$  first integrals of the given equations, or, what we may call the integral functions, being those functions of the co-ordinates, and the time, which remain equal to arbitrary constants during the entire movement.

Let us now, for generality, once more represent the  $6n$  arbitrary constants by

$$a_1, a_2, \dots a_{6n}$$

and let us consider the  $(6n)^2$  quantities of Poisson formed from the general expression<sup>1</sup>

$$[a_\mu, a_\nu] = \sum'_k \left[ \frac{\partial a_\mu}{\partial \xi_k} \frac{\partial a_\nu}{\partial \zeta'_k} - \frac{\partial a_\mu}{\partial \zeta'_k} \frac{\partial a_\nu}{\partial \xi_k} \right], \tag{27}$$

the symbol  $\sum'_k$  including, as in (14), the  $3\mu$  values of  $\xi, \eta$ , and  $\zeta$  in succession. Putting the general expression (14) in the form

$$(a_i, a_j) = \sum'_s \left[ \frac{\partial \xi_s}{\partial a_i} \frac{\partial \zeta'_s}{\partial a_j} - \frac{\partial \zeta'_s}{\partial a_i} \frac{\partial \xi_s}{\partial a_j} \right],$$

forming by multiplication the product of this expression by (27), then putting  $\nu = j$ , and forming the summation

$$\sum_{j=1}^{j=6n} (a_\mu, a_j) (a_i, a_j),$$

noticing also that the expression

$$\sum_{j=1}^{j=6n} \frac{\partial x}{\partial a_j} \frac{\partial a_j}{\partial y}$$

is equal to unity whenever  $x$  and  $y$  represent the same symbol, and to zero in the opposite case, we find

$$\sum_1^{6n} (a_i, a_j) [a_\mu, a_j] = \sum_s \left[ \frac{\partial \xi_s}{\partial a_i} \frac{\partial a_\mu}{\partial \xi_s} + \frac{\partial \zeta'_s}{\partial a_i} \frac{\partial a_\mu}{\partial \zeta'_s} \right],$$

an expression which is itself equal to unity when  $\mu = i$ , and which vanishes in all other cases.

Now  $a_i, a_j$ , and  $a_\mu$  may here be any of the  $6n$  arbitrary constants. Let us then suppose  $a_i, a_\mu$  to represent  $l_i$  and  $l_\mu$  respectively, and  $a_j$  to represent  $c_j$ . This equation will then become

$$(l_i, c_1) [l_\mu, c_1] + (l_i, c_2) [l_\mu, c_2] + (l_i, c_3) [l_\mu, c_3] + \text{etc.} = 1 \text{ or } 0$$

<sup>1</sup> It will be observed that the notations introduced by Lagrange and Poisson respectively, are here reversed, a proceeding which was not intentional on the part of the writer

according as  $i$  and  $\mu$  represent the same or different indices. But we have already found that the expression  $(l_i c_j)$  vanishes whenever  $i$  is different from  $j$ , and reduces to unity when those indices are equal. The equations we are considering thus become

$$[l_i, c_i] = 1, \quad (28)$$

while all other combinations  $[l_i, c_j]$ ,  $[l_i, l_j]$  and  $[c_i, c_j]$  vanish.

Let us now return to the integral equations (26), and first form the combination

$$\begin{aligned} [l_i, c_j] &= \sum_k \left[ \left( \frac{\partial \Psi_i}{\partial \xi_k} - t \frac{\partial b_i}{\partial \xi_k} \right) \frac{\partial \phi_j}{\partial \xi_k} - \left( \frac{\partial \Psi_i}{\partial \xi_k} - t \frac{\partial b_i}{\partial \xi_k} \right) \frac{\partial \phi_j}{\partial \xi_k} \right] \\ &= [\Psi_i, \phi_j] - t [b_i, \phi_j]. \end{aligned}$$

The conditions (28) therefore give

$$[\Psi_i, \phi_j] = 0 \quad (29)$$

and

$$[\Psi_i, \phi_i] = 1,$$

the first equation applying whenever  $j$  is different from  $i$ , the second when they are the same.

Let us next consider the combination  $[l_i, l_j]$  which we know must vanish for all values of  $i$  and  $j$ . Forming the general expression (27) from the integrals (26), we find:—

$$[l_i, l_j] = [\Psi_i, \Psi_j] - t \left\{ [b_i, \Psi_j] - [b_j, \Psi_i] \right\} + t^2 [b_i, b_j] = 0.$$

This equation being identically zero, the coefficient of each power of  $t$  must vanish identically. This gives, in the case of the middle term,

$$[b_i, \Psi_j] = [b_j, \Psi_i]. \quad (30)$$

Forming these expressions by the general formula (27), and putting

$$\frac{\partial b_i}{\partial \xi} = \sum_k \frac{\partial b_i}{\partial c_k} \frac{\partial c_k}{\partial \xi},$$

we find

$$\begin{aligned} [b_i, \Psi_j] &= \sum_1^{3n} \left[ \phi_k, \Psi_j \right] \frac{\partial b_i}{\partial c_k} \\ [b_j, \Psi_i] &= \sum_1^{3n} \left[ \phi_k, \Psi_i \right] \frac{\partial b_j}{\partial c_k}. \end{aligned}$$

By (29) all the terms of these expressions vanish except that one in the first equation in which  $k = j$ , and that one in the second in which  $k = i$ , in both of which the first coefficient reduces to  $-1$ . Hence

$$\begin{aligned} [b_i, \Psi_j] &= - \frac{\partial b_i}{\partial c_j} \\ [b_j, \Psi_i] &= - \frac{\partial b_j}{\partial c_i}, \end{aligned}$$

and (30) now gives

$$\frac{\partial b_i}{\partial c_j} = \frac{\partial b_j}{\partial c_i}. \quad (31)$$

§ 6. *Development of  $\Omega$ ,  $\Omega_j$ , and  $\Omega'_j$ .*

We have next to find the forms of the expressions  $\Omega_j$  and  $\Omega'_j$  which enter into the equations (23) and (24). In the first place we have

$$\Omega = \sum_1^n \frac{m_i m_j}{\sqrt{(x_i - x_j)^2 + (y_i - y_j)^2 + (z_i - z_j)^2}}.$$

We now substitute for  $x, y,$  and  $z$  their expressions (9) as linear functions of  $\xi, \eta,$  and  $\zeta$  respectively. By this substitution we shall introduce no terms of the form  $\xi\eta, \eta\zeta,$  or  $\zeta\xi$ . Hence, when we substitute for  $\xi, \eta,$  and  $\zeta,$  their expressions in infinite periodic series, the reduced expressions will contain cosines only. In fact, using the forms

$$\begin{aligned} \xi_i &= Sk_i \cos N \\ \eta_i &= Sk_i \sin N \\ \zeta_i &= Sk'_i \sin N', \end{aligned}$$

we shall have from (12) when we put for brevity

$$\begin{aligned} \left(\frac{\alpha_{1i}}{m_i} - \frac{\alpha_{1j}}{m_j}\right)k_1 + \left(\frac{\alpha_{2i}}{m_i} - \frac{\alpha_{2j}}{m_j}\right)k_2 + \text{etc.} \dots &= k_{ij}, \\ x_i - x_j &= Sk_{ij} \cos N; \\ y_i - y_j &= Sk_{ij} \sin N; \\ z_i - z_j &= Sk'_i \sin N'. \end{aligned} \tag{32}$$

Each denominator in  $\Omega$  will therefore assume the form

$$\sqrt{(Sk \cos N)^2 + (Sk \sin N)^2 + (Sk' \sin N')^2}.$$

When we form these three squares we find that every term of the form  $h \cos(N_\mu + N_\nu)$  in the first square is destroyed by a corresponding term  $-h \cos(N_\mu + N_\nu)$  in the second square. Hence the sum of these two squares will only contain terms of the form

$$h \cos(N_\mu - N_\nu).$$

Since in each value (15) of  $N$  we have

$$i_1 + i_2 + i_3 + \dots + i_{3n} = 1,$$

we shall have in  $N_\mu - N_\nu$

$$\Sigma i = 0.$$

Also, since in  $N'$  the sum of these coefficients is zero, it follows that the same thing will hold true of the third of the preceding squares. The denominator in question may therefore be expressed in the form

$$\sqrt{Sk \cos N},$$

in which each  $N$  is of the form

$$i_1 \lambda_1 + i_2 \lambda_2 + \dots + i_{3n} \lambda_{3n},$$

where

$$i_1 + i_2 + i_3 + \dots + i_{3n} = 0.$$

The possibility of developing the reciprocal of this denominator in the usual way depends upon the condition that the constant term of  $Sk \cos N$  is larger than the sum of the coefficients of all the other terms, a condition which, so far as we yet know, is fulfilled by all the planets and satellites of our system. Representing this constant term by  $k_0$ , and the quotient of the sum of all the other terms divided by  $k_0$  by  $\Delta$ , so that

$$Sk \cos N = k_0(1 + \Delta)$$

the developed expression for  $\Omega$  will be

$$\Omega = \sum \frac{m_i m_j}{k_0^2} \left( 1 - \frac{1}{2} \Delta + \frac{1.3}{2.4} \Delta^2 - \text{etc.} \right).$$

When we develop the powers of  $\Delta$  this equation will reduce itself to the form

$$\Omega = S h \cos (i_1 \lambda_1 + i_2 \lambda_2 + i_3 \lambda_3 + \dots + i_{3n} \lambda_{3n}), \quad (33)$$

each  $\lambda$  being, as before, of the form

$$\lambda_i = l_i + b_i t,$$

while in each term

$$i_1 + i_2 + i_3 + \dots + i_{3n} = 0.$$

To form the second part of  $\Omega_j$  and of  $\Omega'_j$  in (23) and (24) we have to differentiate the expressions (12) twice with respect to the time, and once with respect to the arbitrary constants which enter into them. Putting, as before, for brevity,

$$\begin{aligned} N &= i_1 \lambda_1 + i_2 \lambda_2 + \dots + i_{3n} \lambda_{3n} \\ b &= i_1 b_1 + i_2 b_2 + \dots + i_{3n} b_{3n}, \end{aligned}$$

we have

$$\begin{aligned} \frac{\partial^2 \zeta_i}{\partial t^2} &= -S b^2 k_i \cos N \\ \frac{\partial^2 \eta_i}{\partial t^2} &= -S b^2 k_i \sin N \\ \frac{\partial^2 \xi_i}{\partial t^2} &= -S b^2 k'_i \sin N'. \end{aligned} \quad (34)$$

For the other derivatives which enter into  $\Omega'_j$  we have

$$\begin{aligned} \frac{\partial \zeta_i}{\partial l_j} &= -S i'_j k_i \sin N \\ \frac{\partial \eta_i}{\partial l_j} &= S i'_j k_i \cos N \\ \frac{\partial \xi_i}{\partial l_j} &= S j'_j k'_i \cos N'. \end{aligned} \quad (34')$$

Forming the sum of the products which enter into  $\Omega_j$ , in the manner represented in § 4, it becomes

$$\sum_{i=1}^{i=n} S_\mu S_\nu \left\{ (i_j k_i)_\nu (b^2 k_{i\mu}) \sin (N_\nu - N_\mu) + \frac{1}{2} (j_j k'_i)_\nu (b^2 k'_i)_\mu (\sin (N'_\nu - N'_\mu) - \sin (N'_\nu + N'_\mu)) \right\}. \quad (35)$$

This expression reduces to the form  $SH \cos N$ , where in each value of  $N$  we have

$$\Sigma i = 0.$$

In this expression it may be worth while to give the complete value of  $H$  corresponding to any value of  $N$ . The value of the latter is completely determined by the indices  $i_1, i_2$ , etc., which multiply  $\lambda_1, \lambda_2$ , etc., in its expression. Let then

$$N = i_1 \lambda_1 + i_2 \lambda_2 + i_3 \lambda_3 + \dots + i_{3n} \lambda_{3n}$$

represent the value of  $N$  for which we wish to find the corresponding value of  $H_j(i_1, i_2, i_3, \dots, i_{3n})$  by means of (35). The required term will be found by taking in (35) all combinations of  $\nu$  and  $\mu$  for which we have

$$\begin{aligned} N_\nu - N_\mu &= N, \\ N'_\nu - N'_\mu &= N, \\ \text{or } N'_\nu + N'_\mu &= N. \end{aligned}$$

Let us represent the combination of indices  $\nu$  in  $N$ , by  $k_1, k_2$ , etc., and those in  $N'$ , by  $j_1, j_2$ , etc., so that we have

$$\begin{aligned} N_\nu &= \mu_1 \lambda_1 + \mu_2 \lambda_2 + \dots + \mu_{3n} \lambda_{3n}, \\ N'_\nu &= j_1 \lambda_1 + j_2 \lambda_2 + \dots + j_{3n} \lambda_{3n}. \end{aligned}$$

Then, in order that the sum or difference of these angles and of  $N_\mu$  may make  $N$ , according to the formulæ just written, we must have

$$N_\mu = (\mu_1 - i_1) \lambda_1 + (\mu_2 - i_2) \lambda_2 + \dots + (\mu_{3n} - i_{3n}) \lambda_{3n}$$

and

$$N'_\mu = (j_1 - i_1) \lambda_1 + (j_2 - i_2) \lambda_2 + \dots + (j_{3n} - i_{3n}) \lambda_{3n}$$

or

$$N'_\mu = (i_1 - j_1) \lambda_1 + (i_2 - j_2) \lambda_2 + \dots + (i_{3n} - j_{3n}) \lambda_{3n}.$$

For the corresponding coefficients of the time  $b$ , we have

$$\begin{aligned} b_\mu &= (\mu_1 - i_1) b_1 + (\mu_2 - i_2) b_2 + \dots + (\mu_{3n} - i_{3n}) b_{3n} \\ b'_\mu &\pm (j_1 - i_1) b_1 \pm (j_2 - i_2) b_2 \pm \dots \pm (j_{3n} - i_{3n}) b_{3n}. \end{aligned}$$

Affecting  $k$  and  $k'$  with the proper indices, as explained in § 4, the part of the coefficient  $H_j(i_1, i_2, \dots, i_{3n})$  corresponding to any one value of the angle  $N_\nu$ , will be

$$\begin{aligned} &\sum_{i=1}^{i=n} \mu_j k_i(\mu_1, \mu_2, \dots) k_i(\mu_1 - i_1, \mu_2 - i_2, \dots) b_\mu^2 \\ &+ \frac{1}{2} \sum_{i=1}^{i=n} j_j k_i(j_1, j_2, \dots) b'_\mu \left\{ k_i(j_1 - i_1, j_2 - i_2, \dots) - k_i(i_1 - j_1, i_2 - j_2, \dots) \right\} \end{aligned}$$

where the values of  $b_\mu$  and  $b'_\mu$  are those just given. The complete value of  $H_j(i_1, i_2, \dots)$  will be found by taking the sum of all the terms which we can form by giving to  $\mu_1, \mu_2$ , etc.,  $j_1, j_2, \dots, j_{3n}$ , in these expressions, all admissible combinations of values, that is, the complete expression will be given by writing before the first line the symbols

$$\begin{array}{ccc} \mu_1 = \infty & \mu_2 = \infty & \mu_{3n} = \infty \\ \sum & \sum & \sum \\ \mu_1 = -\infty & \mu_2 = -\infty & \mu_{3n} = -\infty \end{array} \dots$$

and before the second one

$$\begin{array}{ccccccc} j_1 = \infty & & j_2 = \infty & & & & j_{3n} = \infty \\ \Sigma & & \Sigma & & \dots & & \Sigma \\ j_1 = -\infty & & j_2 = -\infty & & & & j_{3n} = -\infty \end{array}$$

Differentiating (33) with respect to  $l_j$ , we have

$$\frac{\partial \Omega}{\partial l_j} = -S i_j h \sin N. \tag{36}$$

By the substitution of these expressions (23) now assumes the form

$$\frac{dc_j}{dt} = -S h_j \sin N, \tag{37}$$

putting for brevity

$$h = i_j h + H_j.$$

By the fundamental hypothesis that the adopted expressions for  $\xi$ ,  $\eta$ , and  $\zeta$  are first approximations to the true values of those quantities, it follows that in adding (35) and (36) all the terms which are not of the order of those neglected in the first approximation destroy each other, so that  $h$  is of the order of the quantities neglected in that approximation.

To form the equations (24) we differentiate (12) with respect to  $c$ , whereby, omitting the index  $i$  with which  $\xi$ ,  $\eta$ ,  $\zeta$ ,  $k$ , and  $h$  are always to be considered as affected, we find

$$\begin{aligned} \frac{\partial \xi}{\partial c_j} &= S \frac{\partial k}{\partial c_j} \cos N + t S k \frac{\partial b}{\partial c_j} \sin N \\ \frac{\partial \eta}{\partial c_j} &= S \frac{\partial k}{\partial c_j} \sin N + t S k \frac{\partial b}{\partial c_j} \cos N \\ \frac{\partial \zeta}{\partial c_j} &= S \frac{\partial k'}{\partial c_j} \sin N' + t S k' \frac{\partial b'}{\partial c_j} \cos N'. \end{aligned} \tag{37'}$$

The sum of the products of these expressions by (34) which enter into (24) is

$$\begin{aligned} - \sum_{i=1}^{i=n} S^2_{\mu,\nu} \left\{ (b^2 k)_{\mu} \frac{\partial k_{\nu}}{\partial c_j} \cos (N_{\nu} - N_{\mu}) - t (b^2 k)_{\mu} \frac{\partial b_{\nu}}{\partial c_j} \sin (N_{\nu} - N_{\mu}) \right. \\ \left. + \frac{1}{2} (b^2 k')_{\mu} \frac{\partial k'_{\nu}}{\partial c_j} (\cos (N'_{\nu} - N'_{\mu}) - \cos (N'_{\nu} + N'_{\mu})) \right. \\ \left. - \frac{1}{2} t (b^2 k')_{\mu} \frac{\partial b'_{\nu}}{\partial c_j} (\sin (N'_{\nu} - N'_{\mu}) - \sin (N'_{\nu} + N'_{\mu})) \right\}, \end{aligned}$$

while by differentiating (33) we find

$$\frac{\partial \Omega}{\partial c_j} = S \left( \frac{\partial h}{\partial c_j} \cos N - t h \frac{\partial b}{\partial c_j} \sin N \right). \tag{37''}$$

Taking the difference of these two expressions, the equations (24) will assume the form

$$\frac{dl_i}{dt} = -S h'' \cos N + t S h''' \sin N. \tag{38}$$

the quantities  $h''$  and  $h'''$  being formed by a process similar to that used in forming  $h$ . We have now to integrate the expressions (37) and (38), and substitute the

resulting values of  $c_i$  and  $l_i$  in the expressions (12). Representing the perturbations of each quantity by the sign  $\delta$ , we shall have to increase each value of  $\lambda$  by the quantity

$$\delta\lambda_i = \delta l_i + t\delta b_i.$$

We here have the time  $t$  outside the signs *sin* or *cos* in both  $\delta l_i$ , from the integration of (38), and in  $t\delta b_i$ . We must next find the sum of the terms thus introduced into  $\delta\lambda_i$ . Differentiating this expression we have

$$\delta \frac{d\lambda_i}{dt} = \frac{dl_i}{dt} + t \frac{db_i}{dt} + \delta b_i. \tag{39}$$

We have now to form the sum of the terms in the second member of this equation which are multiplied by  $t$ . Beginning with the second, we have, omitting the index of  $b$

$$\frac{db}{dt} = \frac{\partial b}{\partial c_1} \frac{dc_1}{dt} + \frac{\partial b}{\partial c_2} \frac{dc_2}{dt} + \text{etc.}$$

Substituting for  $\frac{dc_i}{dt}$  their values in (37), this equation becomes

$$\frac{db}{dt} = S \left\{ h_1 \frac{\partial b}{\partial c_1} + h_2 \frac{\partial b}{\partial c_2} + \dots + h_{3n} \frac{\partial b}{\partial c_{3n}} \right\} \sin N,$$

which, after multiplying by  $t$ , is to be added to the last member of (38). But it will be more convenient, instead of using  $h$  and  $h''$  in these expressions, to retain the expressions  $\frac{d^2\xi}{dt^2}$ ,  $\frac{d^2\eta}{dt^2}$ , and  $\frac{d^2\zeta}{dt^2}$  in their present analytical form. Representing them,

for brevity, by  $\xi''$ ,  $\eta''$ , and  $\zeta''$ , the equations (23) and (24) become

$$\begin{aligned} \frac{dc_j}{dt} &= \frac{\partial \Omega}{\partial l_j} - \sum_{i=1}^{i=n} \left\{ \xi''_i \frac{\partial \xi_i}{\partial l_j} + \eta''_i \frac{\partial \eta_i}{\partial l_j} + \zeta''_i \frac{\partial \zeta_i}{\partial l_j} \right\} \\ \frac{dl_j}{dt} &= -\frac{\partial \Omega}{\partial c_j} + \sum_{i=1}^{i=n} \left\{ \xi''_i \frac{\partial \xi_i}{\partial c_j} + \eta''_i \frac{\partial \eta_i}{\partial c_j} + \zeta''_i \frac{\partial \zeta_i}{\partial c_j} \right\}. \end{aligned} \tag{40}$$

If in the first of these equations we substitute for the derivatives their values in (34) and (36), it becomes

$$\frac{\partial c_j}{dt} = -S \left\{ i_j h - \sum (\xi''_i i_j k_i) \right\} \sin N + \sum (\eta''_i i_j k_i) \cos N + \sum (\zeta''_i j_j k_i) \cos N'.$$

Substituting in the first of the above expressions for  $\frac{db}{dt}$ , we have

$$\begin{aligned} \frac{db}{dt} &= -S \left\{ i_1 \frac{\partial b}{\partial c_1} + i_2 \frac{\partial b}{\partial c_2} + \dots + i_{3n} \frac{\partial b}{\partial c_{3n}} \right\} h \sin N \\ &+ S \left\{ \sum k_i \xi''_i \left( i_1 \frac{\partial b}{\partial c_1} + i_2 \frac{\partial b}{\partial c_2} + \dots + i_{3n} \frac{\partial b}{\partial c_{3n}} \right) \right\} \sin N \\ &- S \left\{ \sum k_i \eta''_i \left( i_1 \frac{\partial b}{\partial c_1} + i_2 \frac{\partial b}{\partial c_2} + \dots + i_{3n} \frac{\partial b}{\partial c_{3n}} \right) \right\} \cos N \\ &- S \left\{ \sum k_i \zeta''_i \left( j_1 \frac{\partial b}{\partial c_2} + j_2 \frac{\partial b}{\partial c_2} + \dots + j_{3n} \frac{\partial b}{\partial c_{3n}} \right) \right\} \cos N'. \end{aligned} \tag{41}$$

We have next, in the second of equations (40) to substitute the expressions for the derivatives in (37)' and (37)', retaining only the terms multiplied by  $t$ . This gives by substituting for  $b$  its developed expression

$$\begin{aligned}
 b &= i_1 b_1 + i_2 b_2 + \dots + i_{3n} b_{3n} \\
 \frac{1}{t} \frac{dl_i}{dt} &= S \left\{ i_1 \frac{\partial b_1}{\partial c_i} + i_2 \frac{\partial b_2}{\partial c_i} + \dots + i_{3n} \frac{\partial b_{3n}}{\partial c_i} \right\} h \sin N \\
 &- S \left\{ \sum \xi'' h_i \left( i_1 \frac{\partial b_1}{\partial c_i} + i_2 \frac{\partial b_2}{\partial c_i} + \dots + i_{3n} \frac{\partial b_{3n}}{\partial c_i} \right) \right\} \sin N \quad (42) \\
 &+ S \left\{ \sum \eta'' h_i \left( i_1 \frac{\partial b_1}{\partial c_i} + i_2 \frac{\partial b_2}{\partial c_i} + \dots + i_{3n} \frac{\partial b_{3n}}{\partial c_i} \right) \right\} \cos N \\
 &+ S \left\{ \sum \zeta'' h_i \left( j_1 \frac{\partial b_1}{\partial c_i} + j_2 \frac{\partial b_2}{\partial c_i} + \dots + j_{3n} \frac{\partial b_{3n}}{\partial c_i} \right) \right\} \cos N'.
 \end{aligned}$$

Adding this expression to (41), we find that the sum reduces to a series of terms each of which has a factor of the form

$$\frac{\partial b_i}{\partial c_j} - \frac{\partial b_j}{\partial c_i}.$$

By (31) these factors are all zero. Hence the terms of (39) multiplied by  $t$  destroy each other, and we have

$$\delta \frac{d\lambda_i}{dt} = \left( \frac{dl_i}{dt} \right) + \delta b_i, \quad (43)$$

the parenthesis around  $\frac{dl_i}{dt}$  indicating that all the terms multiplied by the time in that expression are to be omitted; in other words, that, in taking the derivatives of  $\Omega$ ,  $\xi$ ,  $\eta$ , and  $\zeta$  with respect to  $c_i$ , we are only to consider the coefficients  $h$ ,  $k$ , and  $k'$  as functions of these quantities, and are not to vary  $b_1$ ,  $b_2$ , etc.

### § 7. Form of the Second Approximation.

The rest of our process is now as follows: By integrating (37) and (38), the last member of (38) being omitted, we have

$$\begin{aligned}
 \delta c_j &= S \frac{h'_j}{b} \cos N \\
 (\delta l_j) &= - S \frac{h''_j}{b} \sin N.
 \end{aligned}$$

The co-ordinates  $\xi$ ,  $\eta$ , and  $\zeta$  in (12) being expressed as functions of the quantities  $c_j$  and  $l_j$ , we are to suppose these quantities increased by their perturbations, that is, we are to find

$$\delta \xi = \sum \frac{\partial \xi}{\partial c_j} \delta c_j + \sum \frac{\partial \xi}{\partial l_j} \delta l_j,$$

or, since we have replaced  $l_i$  by  $\lambda_i$ ,

$$\delta \xi = \sum \frac{\partial \xi}{\partial c_j} \delta c_j + \sum \frac{\partial \xi}{\partial \lambda_j} \delta \lambda_j.$$

In (43) we have

$$\delta b_i = \sum_j \frac{\partial b_i}{\partial c_j} \delta c_j = S \sum_{j=1}^{j=3n} \frac{h'_j}{b} \frac{\partial b_i}{\partial c_j} \cos N,$$

and, integrating,

$$\begin{aligned} \delta \lambda_i &= (\delta l_i) + \int \delta b_i dt \\ &= -S \left\{ \frac{h''_i}{b} - \sum_{j=1}^{j=3n} \frac{h'_j}{b^2} \frac{\partial b^i}{\partial c_j} \right\} \sin N, \end{aligned}$$

which, for brevity, we may represent by

$$\delta \lambda_i = S_i L_i \sin N, \tag{44}$$

putting

$$L_i = -\frac{h''_i}{b} + \sum_{j=1}^{j=3n} \frac{h'_j}{b^2} \frac{\partial b_i}{\partial c_j}.$$

In adding the effect of the perturbations  $\delta c_i$  to  $\xi$ ,  $\eta$ , and  $\zeta$ , we are to vary only  $l$ , the expressions for  $\delta \xi$ , etc., being

$$\begin{aligned} \delta \xi &= S_\mu \left\{ \delta k \cos N - k \sin N (i_1 \delta \lambda_1 + i_2 \delta \lambda_2 + \dots + i_{3n} \delta \lambda_{3n}) \right\} \\ \delta \eta &= S_\mu \left\{ \delta k \sin N + k \cos N (i_1 \delta \lambda_1 + i_2 \delta \lambda_2 + \dots + i_{3n} \delta \lambda_{3n}) \right\} \\ \delta \zeta &= S_\mu \left\{ \delta k' \sin N' + k' \cos N' (j_1 \delta \lambda_1 + j_2 \delta \lambda_2 + \dots + j_{3n} \delta \lambda_{3n}) \right\} \end{aligned}$$

We are to put in these expressions

$$\begin{aligned} \delta k &= \sum_i \frac{\partial k}{\partial c_i} \delta c_i \\ &= S_i \left( \sum_i \frac{h'_i}{b} \frac{\partial k'}{\partial c_i} \right) \cos N, \end{aligned} \tag{45}$$

and the values of  $\delta \lambda$  in (44). We thus find

$$\begin{aligned} \delta \xi &= \frac{1}{2} S^2_{\mu, \nu} \left\{ \sum_i \left( \frac{h'_i}{b} \frac{\partial k}{\partial c_i} \right)_\nu + k_{\mu} (i_1 L_1 + i_2 L_2 + \dots + i_{3n} L_{3n})_\nu \right\} \cos (N_\mu + N_\nu) \\ &\quad + \frac{1}{2} S^2_{\mu, \nu} \left\{ \sum_i \left( \frac{h'_i}{b} \frac{\partial k}{\partial c_i} \right)_\nu - k_{\mu} (i_1 L_1 + i_2 L_2 + \dots + i_{3n} L_{3n})_\nu \right\} \cos (N_\mu - N_\nu) \\ \delta \eta &= \frac{1}{2} S^2_{\mu, \nu} \left\{ \sum_i \left( \frac{h'_i}{b} \frac{\partial k}{\partial c_i} \right)_\nu + k_{\mu} (i_1 L_1 + i_2 L_2 + \dots + i_{3n} L_{3n})_\nu \right\} \sin (N_\mu + N_\nu) \\ &\quad + \frac{1}{2} S^2_{\mu, \nu} \left\{ \sum_i \left( \frac{h'_i}{b} \frac{\partial k}{\partial c_i} \right)_\nu - k_{\mu} (i_1 L_1 + i_2 L_2 + \dots + i_{3n} L_{3n})_\nu \right\} \sin (N_\mu - N_\nu) \\ \delta \zeta &= \frac{1}{2} S^2_{\mu, \nu} \left\{ \sum_i \left( \frac{h'_i}{b} \frac{\partial k'}{\partial c_i} \right)_\nu + k'_{\mu} (j_1 L_1 + j_2 L_2 + \dots + j_{3n} L_{3n})_\nu \right\} \sin (N'_\mu + N'_\nu) \\ &\quad + \frac{1}{2} S^2_{\mu, \nu} \left\{ \sum_i \left( \frac{h'_i}{b} \frac{\partial k'}{\partial c_i} \right)_\nu - k'_{\mu} (j_1 L_1 + j_2 L_2 + \dots + j_{3n} L_{3n})_\nu \right\} \sin (N'_\mu - N'_\nu) \end{aligned}$$

Since, in  $N_\mu$  we have  $\sum i = 1$ ,  
while in  $N_\nu$  “ “  $\sum i = 0$ ,

it follows that all these terms will be of the same form with those already contained in  $\xi$ ,  $\eta$ , and  $\zeta$  (12).

In the preceding integration we have tacitly supposed the coefficient of the time,  $b$ , never to vanish in any case. But some of the values of  $N$  will necessarily be zero, and in this case, instead of having

$$\int k dt \cos N = \frac{k}{b} \sin N,$$

we must put

$$\int k dt \cos N = kt.$$

The only terms of this form are found in  $\delta l$ . If, in (38), we represent the coefficient of the vanishing term by  $h''_0$ , we shall have for the terms in question

$$\delta l = -h''_0 t.$$

This adds to  $\lambda$  the same expression, and is equivalent to diminishing  $b$  by the quantity  $h''_0$ . We make this change not only in the original terms of  $\xi$ ,  $\eta$ , and  $\zeta$ , but also in the terms of  $\delta\xi$ ,  $\delta\eta$ , and  $\delta\zeta$ , because the change will only affect them by quantities of the second order, which we have rejected throughout.

Making these changes, the expressions

$$\xi + \delta\xi, \quad \eta + \delta\eta, \quad \text{and} \quad \zeta + \delta\zeta,$$

will now satisfy the differential equations (11) to quantities of the second order, while their form will still be in all respects the same as in (12). As we have made this one approximation without changing the form of the original integrals, so may we make any number of successive approximations. We may, therefore, regard the form

$$\begin{aligned} \xi &= Sk \cos (i_1\lambda_1 + i_2\lambda_2 + \dots + i_{3n}\lambda_{3n}) \\ \eta &= Sk \sin (i_1\lambda_1 + i_2\lambda_2 + \dots + i_{3n}\lambda_{3n}) \\ \zeta &= Sk \sin (j_1\lambda_1 + j_2\lambda_2 + \dots + j_{3n}\lambda_{3n}), \end{aligned}$$

where each  $\lambda$  is of the form

$$\lambda_i = l_i + b_i t,$$

$l_i$  being an arbitrary constant, and  $k$ ,  $k'$ , and  $b_i$  being each functions of  $3n$  other arbitrary constants, while

$$\begin{aligned} i_1 + i_2 + \dots + i_{3n} &= 1, \\ \text{and } j_1 + j_2 + \dots + j_{3n} &= 0, \end{aligned}$$

in each separate term under the sign  $S$ , to be a general form in which the relative co-ordinates of  $n$  planets, revolving in nearly circular orbits with a nearly uniform motion, may be developed when the approximations are continued indefinitely. This may, therefore, be regarded as the general form of the integrals of planetary motion.

### § 8. General Theorem.

*If we express the relative living force of the entire system in terms of the canonical elements, the coefficients of the time  $b_1, b_2, \dots, b_{3n}$  will each be equal to the negative*

of the derivative of the constant term of the living force with respect to its corresponding canonical element. That is to say, if we represent the constant term of the living force by  $V$ , and suppose  $V$  to be expressed in terms of the canonical elements, we shall have

$$\begin{aligned} b_1 &= -\frac{\partial V}{\partial c_1} \\ b_2 &= -\frac{\partial V}{\partial c_2} \\ &\vdots \\ b_{3n} &= -\frac{\partial V}{\partial c_{3n}} \end{aligned}$$

From the expressions (9) for  $x$ , and the corresponding expressions for  $y$  and  $z$ , it will be seen that the expression for the relative living force is

$$\begin{aligned} &\frac{1}{2} \left( \frac{\alpha_{10}}{\sqrt{m_0}} \zeta'_1 + \frac{\alpha_{20}}{\sqrt{m_0}} \zeta'_2 + \dots \right)^2 \\ &+ \frac{1}{2} \left( \frac{\alpha_{11}}{\sqrt{m_1}} \zeta'_1 + \frac{\alpha_{21}}{\sqrt{m_1}} \zeta'_2 + \dots \right)^2 \\ &+ \quad \text{etc.} \quad \text{etc.} \quad \text{etc.} \\ &+ \text{corresponding terms in } \eta' \text{ and } \zeta'. \end{aligned}$$

Here the coefficients of  $\zeta'$ , etc., are those which we have shown to form an orthogonal system, and, by the properties of such a system, the expression reduces to

$$\frac{1}{2} \sum_i (\xi'^2_i + \eta'^2_i + \zeta'^2_i).$$

Substituting for  $\xi'$ ,  $\eta'$ , and  $\zeta'$  their periodic expressions

$$\begin{aligned} \xi' &= -Sbk \sin N \\ \eta' &= Sbk \cos N \\ \zeta' &= S'k' \cos N', \end{aligned}$$

the constant term of the living force is found to be

$$V = \frac{1}{2} S' (b^2 k'^2 + \frac{1}{2} b^2 k^2),$$

the sign  $S'$  having the signification given on page 12. Compare this expression with that of  $c_i$  in (21). Multiply each  $c_i$  by its corresponding  $b_i$ , and add all the products, remembering that

$$\begin{aligned} b &= i_1 b_1 + i_2 b_2 + \text{etc. for } \xi \text{ and } \eta, \text{ and} \\ b &= j_1 b_1 + j_2 b_2 + \text{etc. for } \zeta. \end{aligned}$$

We thus find, from the expression for  $V$  just given,

$$2V = b_1 c_1 + b_2 c_2 + b_3 c_3 + \dots + b_{3n} c_{3n}.$$

Differentiating this expression with respect to  $c_i$  and substituting  $\frac{\partial b_i}{\partial c_j}$  for  $\frac{\partial b_j}{\partial c_i}$ , we have

$$2 \frac{\partial V}{\partial c_i} = b_i + c_1 \frac{\partial b_i}{\partial c_1} + c_2 \frac{\partial b_i}{\partial c_2} + \dots + c_{3n} \frac{\partial b_i}{\partial c_{3n}}. \quad (46)$$

We have now to show that  $b$  is a homogeneous function of the degree  $-3$  in  $(c_1, c_2, \dots, c_{3n})$ . Let us represent such a function of the  $n$ th degree by  $[c^{(n)}]$

Let us represent the linear elements of the system by  $a_1, a_2$ , etc. Since  $x, y, z$ , and  $\xi, \eta, \zeta$ , are all linear co-ordinates, we have in the expressions (16) of the latter

$$k = [a^{(1)}].$$

Every time we differentiate these expressions with respect to the time, we multiply the coefficients by  $b$ , a linear function of  $b_1, b_2$ , etc. Hence

$$\frac{d^2\xi}{dt^2} = [a^{(1)}, b^{(2)}].$$

The form of the potential  $\Omega$  shows that

$$\Omega = [a^{(-1)}],$$

a result which arises from the law of attraction proportional to the inverse square of the distance. Whence

$$\frac{\partial\Omega}{\partial\xi} = [a^{(-2)}].$$

In order that the differential equation  $\frac{d^2\xi}{dt^2} = \frac{\partial\Omega}{\partial\xi}$  may be satisfied identically we must have

$$[a^{(1)}, b^{(2)}] = [a^{(-2)}],$$

or

$$b^{(2)} = [a^{(-3)}] \text{ or } b = [a^{(-3)}].$$

The expression (21) for  $e_i, k$  being linear in  $a$ , is of the form

$$e_i = [b^{(1)} a^{(2)}] = [a^{(3)}] = [b^{(-3)}].$$

Hence, when we express  $b_i$  in terms of  $e_1, e_2$ , etc., we must have

$$b_i = [c^{(-3)}].$$

The fundamental property of homogeneous functions now gives

$$\sum_j e_j \frac{\partial b_i}{\partial e_j} = -3b_i.$$

Substituting in (46), we find

$$b_i = -\frac{\partial V}{\partial c_i},$$

which is the theorem enunciated.

This theorem cannot be directly employed to obtain the values of  $b_i$ , for the reason that  $V$  cannot be determined as a function of the canonical constants until the equations of motion are completely integrated.

### § 9. *Summary of Results.*

The following is a brief summary of some of the results which follow from the preceding investigation.

We first suppose that we have found expressions for  $\xi, \eta$ , and  $\zeta$  of the form (12), such as identically satisfy the differential equations (11). We also conceive the

quantities  $k$  and  $b$  as expressed in terms of  $3n$  canonical constants  $c_1, c_2, c_3, \dots, c_{3n}$ , so chosen that the expression

$$(c_j, l_k) = \sum_{i=1}^{i=n} \left\{ \frac{\partial \xi_i}{\partial c_j} \frac{\partial \xi'_i}{\partial l_k} - \frac{\partial \xi'_i}{\partial c_k} \frac{\partial \xi_i}{\partial l_j} + \frac{\partial \eta_i}{\partial c_j} \frac{\partial \eta'_i}{\partial l_k} - \text{etc.} \right\}$$

shall reduce to unity when  $k=j$ , and shall vanish whenever any other of the  $6n$  quantities  $c_1, \dots, c_{3n}, l_1, \dots, l_{3n}$  is substituted for  $l_k$ . Then:—

*Theorem I.*—If, taking the entire series of  $3n$  co-ordinates represented by  $\xi_1, \dots, \xi_n, \eta_1, \dots, \eta_n, \zeta_1, \dots, \zeta_n$ , we multiply the square of each coefficient  $k$  by the coefficient of the time in the corresponding angle  $i_1\lambda_1 + i_2\lambda_2 + \text{etc.}$  (that is, by the corresponding quantity  $i_1b_1 + i_2b_2 + \text{etc.}$ , or  $j_1b_1 + j_2b_2 + \text{etc.}$ ), and by the coefficient  $i_j$  or  $j_j$  of any one of the  $\lambda$ 's, as  $\lambda_j$ , which  $\lambda$  is to be the same throughout, then all the constants  $c$ , except  $c_j$ , will identically disappear from the sum of all these products, which sum will reduce identically to  $2c_j$ . This theorem is expressed in equation (21).

*Theorem II.*—The  $3n$  coefficients of the time,  $b_1, b_2, \text{etc.}$ , considered as functions of  $c_1, c_2, \text{etc.}$ , fulfil the  $\frac{3n(3n-1)}{2}$  conditions expressed by

$$\frac{\partial b_i}{\partial c_j} = \frac{\partial b_j}{\partial c_i},$$

where  $i$  and  $j$  may have any values at pleasure from 1 to  $3n$ . They are therefore all the partial derivatives of some one function of  $c_1, c_2, \dots, c_{3n}$ .

*Theorem III.*—This function is the negative of the constant term of the expression for the living force in terms of  $c_1, c_2, \text{etc.}$ , as shown in the last section.

*Theorem IV.*—The sum of the canonical elements  $c_1, c_2, \dots, c_{3n}$  is equal to the “constant of areas,” this constant being either the sum of the canonical areolar velocities on the plane of  $XY$ , or, which is the same, the sum of the products obtained by multiplying the actual areolar velocity of each body around any point, fixed with reference to the centre of gravity of the system, by the mass of the body.

This theorem is demonstrated as follows: The sum

$$\sum_{i=0}^{i=n} m_i (x_i y'_i - x'_i y_i)$$

is known to be a constant by the principle of conservation of areas. From the expression (9) for  $x_i$ , and the corresponding expression for  $y_i$ , introducing the quantity  $\alpha_{0i}$  as in (8), we have

$$(x_i y'_i - x'_i y_i) = \sum_{j=0}^{j=n} \sum_{k=0}^{k=n} \frac{\alpha_{ji} \alpha_{ki}}{m_i^2} (\xi_j \eta'_k - \xi'_j \eta_k);$$

multiplying by  $m_i$ , and then summing with respect to  $i$ , we have

$$\sum m_i (x_i y'_i - x'_i y_i) = \sum_{j=0}^{j=n} \sum_{k=0}^{k=n} \left\{ \sum_{i=0}^{i=n} \frac{\alpha_{ji} \alpha_{ki}}{m_i} \right\} (\xi_j \eta'_k - \xi'_j \eta_k).$$

By the condition of the orthogonal system (8) the sum in brackets vanishes whenever  $j$  is different from  $k$ , and becomes unity when these indices are equal. Moreover in (5)  $\xi'_0$  and  $\eta_0$  vanish whenever the origin of co-ordinates is fixed relatively

to the centre of gravity of the system. The right-hand member of the last equation therefore becomes

$$\sum_{j=1}^{j=n} (\xi_j \eta'_j - \xi'_j \eta_j).$$

Substituting for  $\xi$ ,  $\eta$ ,  $\xi'$ , and  $\eta'$  their expressions (16), the constant term of this expression becomes

$$S'bk^2.$$

But if we add all the values of  $c_j$  in (21), noting that by the form of the general integrals we have

$$\begin{aligned} i_1 + i_2 + i_3 + \dots + i_{3n} &= 1 \\ j_1 + j_2 + j_3 + \dots + j_{3n} &= 0, \end{aligned}$$

we find, also,

$$\sum c_j = S'bk^2,$$

and hence

$$\Sigma (\xi \eta' - \xi' \eta) = \Sigma c.$$

*Theorem V.*—The constant part of the living force, which is itself equal to the constant  $H$  in the integral of living forces, usually expressed in the form

$$\Omega - T = H,$$

is represented by

$$\frac{1}{2}(b_1 c_1 + b_2 c_2 + \dots + b_{3n} c_{3n}),$$

as already shown in § 9.

The constant part of  $\Omega$  itself is therefore equal to

$$b_1 c_1 + b_2 c_2 + \dots + b_{3n} c_{3n}.$$

The equality of  $H$  to the constant part of  $T$  may be shown by the preceding theory, or it may be easily deduced directly from the theorem of living forces as shown by Jacobi. (*Vorlesungen über Dynamik*, p. 29.)

The conditions that the Lagrangian coefficients ( $a_i$ ,  $l_j$ ), the sum of the canonical areolar velocities, and the difference between the potential and living force, are all constant, give rise to a number of relations between the quantities  $b$ ,  $k$ , and their derivatives with respect to  $c$ , which I have not yet found of any use in the operations of integration. I therefore omit to cite them, especially as their complete expressions are rather complex.

The forms which we have been considering are those in which it would be necessary to develop the expressions for co-ordinates of the planets, if we wished these expressions to hold true for all time. The usual expressions are sufficiently correct for a few centuries, but fail entirely when we extend the time beyond certain limits. But, in the case of the planetary system, we are obliged to adhere to them for the reason that formulas developed in multiples of the 23\* independent arguments of that system would be unmanageable in practice. But, in the case of the subsidiary systems, as the Tellurian and Jovian for instance, the secular

---

\* A linear relation of which we have not spoken must subsist between the quantities  $\dot{b}_1$ ,  $\dot{b}_2$ , etc., which reduces the number of really independent arguments to  $3n-1$ .

variations of the orbits are so rapid that the approximation in powers of the time fails even for present uses. Hence, the lunar theory, considered as a problem of three bodies only, is always treated in a manner analogous to that in which the general theory of planetary motion has been considered in the present paper, the three arguments introduced by the moon being her mean longitude, and the longitudes of her node and perigee. In the theory of Delaunay the analogy in question is most easily seen. His  $L, G, H$ , represent three of our canonical elements  $c_i$ , the constant term of  $R$ , to which he constantly approximates, is the constant part of so much of the expression for the living force as contains  $L, G$ , and  $H$ , by differentiating which with respect to the latter quantities, he obtains the expressions for the motions of the three arguments.

The theory of Jupiter's satellites has been treated by M. Souillart in such a manner that the co-ordinates may contain, instead of the longitudes of the perijoves, the varying angles on which these longitudes depend. His analytical theory is given in the *Annales de l'Ecole Normale Supérieure*, Vol. 2, 1865.

It may be hoped that the general view of the subject taken in the present paper will afford a means of introducing a more rigorous system of integration in such cases. One of the special problems growing out of this general theory will be the determination of the coefficients of the time,  $b_1, b_2$ , etc., either in terms of the canonical constants  $c_1, c_2$ , etc., or of the largest of the coefficients  $k$ , in the expressions for the co-ordinates of the several planets. These coefficients are, approximately, the mean distances of the planets. The quantities  $b$  ought, perhaps, to appear as the roots of an equation of the  $3n$ th degree, but the writer has not yet succeeded in forming any expression fitted to give rise to such an equation, except one in which only the squares of the quantities in question appear.

THIS Memoir was referred for examination to Dr. James C. Welling, LL.D., President of Columbian University, Washington, D. C., and to Dr. George A. Otis, of the Surgeon General's Office, U. S. Army.

Their report states that "the Memoir is a valuable contribution to our general knowledge of anthropology and archæology, while yielding besides a special contingent to the ethnology of the North American continent. Under the latter of these heads it raises some questions which seem of great significance, and which it is to be hoped will lead to further investigation."

JOSEPH HENRY,

*Secretary S. I.*

SMITHSONIAN INSTITUTION,

Washington, July, 1874.

## THE HAIDAH INDIANS OF QUEEN CHARLOTTE'S ISLANDS.

---

QUEEN CHARLOTTE'S ISLANDS are a group in the Pacific Ocean, lying off the northwest coast of North America about seventy-five miles northwest of Vancouver's Island, between latitude  $51^{\circ} 30'$  and  $54^{\circ} 20'$  north, and at a distance from the mainland varying from one hundred miles at their southern extremity to about sixty miles at the northern portion of the group.

They were first discovered by Captain Cook, R. N., in the year 1776, and it is said that he landed on the most northerly portion near a spot now known as Cook's Inlet. Captain Juan Perez, a Spanish navigator, had sighted this land two years previously, but it was not taken formal possession of by either the English or Spanish until 1787, when Captain Dixon took possession in the name of King George the Third, and named the group after the consort of the King, "Queen Charlotte's Islands."

These Islands form together a healthy picturesque territory, rich in natural resources, and well adapted to colonization. Nevertheless, for the space of nearly a century no attempt has been made by the English to colonize them. There they lie waste and fallow, yet marvellously productive, and awaiting nothing but capital, enterprise, and skill to return manifold profit to those who will develop their resources.

The names of this group are North, Graham's, Moresby's, and Prevost.

Graham's and Moresby's Islands are the largest, and constitute at least 95 per cent. of the whole area of the group.

North and Prevost Islands, one at the extreme northwest, and the other at the extreme southeast of the group, are quite small, being only a few miles in area.

There are a great number of small islands and islets around the main group, particularly on the eastern side. Some of these islets are of considerable extent, but are of minor importance when compared with the main group.

The general direction of Queen Charlotte's Islands is northwest and southeast, following the general outline of the coast in that region of the continent.

The widest portion is at the northern end of Graham's Island, a little north of the  $54^{\circ}$  parallel, and measures, from Cape Fife on the east, to Cape Knox on the west, about sixty nautical miles.

From the  $54^{\circ}$  parallel the group narrows towards its southern extremity till it is reduced, at Prevost Island, to about one mile.

The whole length of the group from North Point to Cape St. James, its southern extremity, is about one hundred and sixty miles. The islands of the group are separated by three channels. Parry Passage, at the north, separates North Island from Graham's, Skidegate Channel separates Graham's and Moresby's Islands, and Stewart Channel separates Moresby's and Prevost Islands.

These Islands are inhabited by a tribe of Indians called Haida or Hydah, who in manners and customs seem somewhat different from the neighboring tribes of the mainland, and those of Vancouver's Island. The name is spelled Hyder, Haida, or Haidah. I have adopted the latter style as it is more expressive of the true pronunciation of the natives.

In general appearance the Haidahs resemble the natives of the northeastern coast of Asia, who have a marked resemblance to the Tartar hordes and who seem to have extended along the Siberian coast, the Aleutian Islands, and down the American shores as far south as Queen Charlotte's Islands, where this peculiar type of the Indian race ceases, and is succeeded immediately by the Selish or flat-head branch of the North American Indians, who have been classed by Morgan as the Ganowanian family or Bow and Arrow people. I apply the term *Selish* in this paper to the tribes of Washington Territory and British Columbia south of the 51° parallel of north latitude.

The distinctive features of these two classes of Indians are apparent to the most casual observer. The Haidah, Chimsean, and other tribes north of Vancouver's Island, who are termed by the residents of Puget Sound "Northern Indians," are, as a general rule, of larger stature, better proportion, and lighter complexion than the Selish.

Although there are numerous instances of well-developed individuals among the Vancouver Island tribes, and of small-sized individuals among the Northern, yet the general appearance of the Northern Indians, both men and women, is much larger and finer. This difference is particularly marked in the females. Those of the Haidah and other northern tribes are tall and athletic, while the Selish women are shorter and more given to corpulency.

The Haidah Indians, living on an island separated from the mainland by a wide and stormy strait, are necessarily obliged to resort to canoes as a means of travel, and are exceedingly expert in their construction and management.

Some of their canoes are very large and capable of carrying one hundred persons with all their equipments for a long voyage. But those generally used will carry from twenty to thirty persons; and in these conveyances they make voyages of several hundred miles to Victoria on Vancouver's Island, and from thence to the various towns on Puget Sound.

These canoes are made from single logs of cedar, which attains an immense size on Queen Charlotte's Islands. Although not so graceful in model as the canoes of the west coast of Vancouver's Island and Washington Territory, which are commonly called Chenook canoes, yet they are most excellent sea boats, and capable of being navigated with perfect safety through the storms and turbulent waters of the northwest coast.

The Haidahs bring with them as articles of traffic, furs of various kinds, dogfish, and seal oil, and carvings in wood and stone, as well as ornaments in silver of excellent workmanship, such as bracelets, finger-rings, and ear ornaments.

A peculiar kind of slate-stone is found on Queen Charlotte's Islands, very soft when first quarried, and easily carved into fanciful figures of various kinds, but growing very hard upon exposure to the air, and after being rubbed with oil, which seems to harden and polish it.

These stone carvings are eagerly purchased by persons looking for Indian curiosities, and are generally regarded by casual observers as idols, or objects of worship, or indicative in some manner of their secret or mystic rites. This, however, is an error. None of the tribes of the northwest coast worship idols or any visible symbol of their secret religion, which is confined to the totem, or tomanawas, or guardian spirit of each individual Indian.

But the custom which prevails among them, and seems to be a distinctive feature of this tribe, is that of tattooing their bodies with various designs, all of which are fanciful representations of animals, birds or fishes, either an attempt to represent in a grotesque form those which are known and commonly seen, or their mythological and legendary creations. A recent visit of a party of these Indians to Port Townsend has enabled me to study carefully a variety of their carvings and tattoo marks, and to ascertain with accuracy their true meaning and signification.

I have forwarded to the Smithsonian Institution, to accompany this memoir, several carvings in wood and stone; and, in order the better to describe them, I have made sketches illustrative of these carvings and also of various tattoo designs, which were copied by me from the persons of the Indians, and also have caused photographs to be taken to still further illustrate this subject.

The first of these carvings which I shall describe is of wood (Plate 2, fig. 1). It is intended to represent one of the carved posts or pillars which are raised in front of the houses of the chiefs or principal men. These pillars are sometimes from fifty to sixty feet high, elaborately carved at a cost of hundreds of blankets; some of the best ones even costing several thousand dollars, consequently, only the most wealthy individuals of the tribe are able to purchase the best specimens.

These pillars are carved out of a single cedar tree, the back hollowed out so as to relieve the weight when raising it in a perpendicular position. They are deeply and firmly set in the earth directly in front of the lodge, and a circular opening near the ground constitutes the door of entrance to the house. The Chimsean Indians, at Fort Simpson, and the Sitka tribes have this style of carved posts, but they set them a short distance from the front of their houses.

The figures carved on these posts are the family totems or heraldic designs of the family occupying the house, and as these Indians build large wooden lodges capable of containing several families, the carvings may be said to indicate the family names of the different occupants.

The chief or head man owns the house, and the occupants are his family and relatives, each one of whom will have on some part of the body a representation in tattooing of the particular figure which constitutes his or her family name or connection.

The chief will have all the figures tattooed on his body to show his connection with the whole.

The principal portion of the body tattooed is the back of the hand and forearm; and a Haidah, particularly the women, can be readily designated from any other northern tribe by this peculiarity.

The carving which I shall next describe is the wooden figure on the left of Sketch No. 2. This has four figures, one above the other. The lowest one is the beaver *Tsching*. On his head sits the mythological mother of the Haidah tribe, who is named *Il-tads-dah*. In her arms she holds the young crow *Keet-kie*, and on her head is seated the crow *Hoo-yéh*, bearing in his beak the new moon *Koong*. His head is surmounted by the *Tadn-skillik*, a peculiar shaped hat worn only by chiefs or persons of importance. On the top of the *Tadn-skillik* is seated the bear *Hoorts*.

The legend connected with this carving is, that the beaver *Tsching* occupies himself by eating the moon, and when he has finished his meal and obliterated it, *Il-tads-dah* sends out *Hoo-yéh*, the crow, to hunt for a new moon which he brings home in his bill. The duty of *Hoorts* the bear is to keep watch that all goes on well.

The second carving is of stone (Plate 1, fig. 1), and consists of *Tsching* the beaver, *Skams-kuwin* the eagle, and *Il-tads-dah* the grandmother. In the under lip of the old woman is seen the *staié*, an oblong piece of wood or ivory which is inserted in the under lip, and increased in size till the lip is distorted and stretched out of all shape.

This practice was formerly universal, but of late years has fallen somewhat into disuse, particularly with those females who have visited Victoria and seen the customs of civilization.

Carving No. 2 is of stone, and represents two figures, the lower one is *Hoorts* the bear holding in his paws the *Stoo* or crayfish. The upper figure is the *Tsching* or *Tsing*, the beaver, holding the *Tl-kam-kostan* or frog in his paws.

The Indian, however rude or grotesque his carvings or paintings may be, is always true to nature. He knows that the bears eat crabs, crayfish, and other littoral marine crustacea, and that the frog is the fresh-water companion of the beaver. Hence, if the carver had reversed the grouping, he would have been laughed at by his friends, for the Indians are keen critics of each other's work, and prone to ridicule.

Stone carving No. 3 represents three figures. The lower one is the *Talm* or sea-lion; on his head is the *Wasko*, a mythological animal of the wolf species similar to the *Chu-chu-lu-uxl* of the Makah Indians. Above the *Wasko* is the bear, surmounted by a head resembling a human head, but intended to represent the young bear.

The other stone carving (Plate 5, No. 5) is unfinished. It represents two figures: the lower one, the bear, and the upper one, the *Scana* or killer (*Orca ater*).

With the exception of the first-named carving, I did not learn of any legend or allegorical history connected with these carvings of the Haidahs. But they will be of interest and value to study at some future opportunity.

The drawings of tattoo designs which accompany the carvings were copied by me from the persons of the Indians who came to my office for that purpose.

The first one (Plate 4, fig. 1) is the *Kahatta* or codfish. This was tattooed on the breast of Kitkūn, a chief of the Laskeek village of Haidahs, on the east side of Moresby's Island.

Kitkūn and his brother Ĝenés-kelos—a carver and tattooer—*Kit-kā-gens*, one of the head men of the band, and Captain Skedance, chief of the Koonā village, with their party gave me the information and descriptions, and from their persons I made the drawings.

Fig. 2 (tattoo mark) is the *Oolala*, a mythological being, half man, half bird, similar in all respects to the Thunder bird of the Makah Indians. It lives on high mountains enveloped in clouds and mist, causing the loud thunder and sharp lightning, and destructive alike to man or beast.

Fig. 3 (Plate 4) is called *Wásko*, another mythological being of the antediluvian age. This represents the ancestors of the present race of wolves. It is similar to the *Chu-chu-hu-uál* of the Makahs, and the tradition is, that after the primitive race had produced the present genus of wolf, the Wasko were transformed into the killer (*orca ater*). The sharp teeth and powerful jaws of the killer, resembling more the mouth of a carnivorous land animal than any of the inhabitants of the water, was undoubtedly the origin of the fable.

Scammon, in his *Cetacea* of the Northwest Coast, styles them the cannibals of the whale tribe. The *Wasko*, as I have copied it, was tattooed on the back of the chief Kitkūn.

Fig. 4 (Plate 4) is the *Scana* or killer (*Orca ater*).

Fig. 5 is the *Koone* or whale.

Plate 5, Fig. 6, is the *Tl-kam-kostan* or frog.

Fig. 7 is the *Thlama* or skate.

Fig. 8, *mama-thlon-tona* or humming bird.

Plate 3, Fig. 9, is the fish eagle (*Koot*). This drawing was made by Ĝeneskelos, the painter and tattooer of the tribe.

Plate 6, Fig. 10, is the *Chimose* or *Tchimose*, a fabulous animal supposed to drift about in the ocean like a log of wood, floating perpendicularly, and believed by the Haidahs to be very destructive to canoes or to Indians who may fall into its clutches. The *tahdn-skillik* or hat shown in the drawing indicates this animal to belong to the genii or more powerful of these mythological beings.

Fig. 11 is the crow, *Hooyeh*. This is sometimes drawn with a double head.

Fig. 12 is the bear, *Hoorts*.

Fig. 13 is a young skate, the *Billachie* of the Makahs and the *Cheetka* of the Haidahs. The young skate has on each side of its body an elliptical brown spot surrounded by a ring of bright yellow, and a brown ring outside of all. As the skate grows large this spot disappears. I have noticed it only on very small ones, and the Haidahs informed me that it is from this peculiar spot that they got their elliptical designs, which are to be seen in many of their paintings, and particularly in Fig. 12.

Figs. 14, 15, and 16 (Plate 7), representing the *Skamsom* or thunder bird, squid

(*octopus*), *noo*, and the frog, *Tl-kam-kostan*, were copied from the tattooed marks on Kitkagens; the *skamson* or *skamsquin* on his back, the *noo* on front of each thigh, and the *Tl-kam-kostan* on each ankle.

The designs which I have copied and described are but a portion of the whole which were tattooed on the persons of this party; but the limited time they remained did not enable me to make a very extended examination. Enough, however, has been obtained to show that this subject is one of great ethnological value, and if followed up with zeal and intelligence would be certain to produce interesting results.

The method by which I determined with accuracy the meaning of these various carvings and tattoo designs was by natural objects, by alcoholic specimens of frogs and crayfish, by dried specimens, by carvings of bears and seals, and by pictures, and by the mythological drawings of similar objects which I had previously obtained and determined among the Makahs.

The Haidahs, in explaining to me the meaning of their various designs, pointed to the articles I had, and thus proved to me what they meant to represent.

The tattoo marks of the codfish, squid, humming-bird, etc., never could have been determined from any resemblance to those objects, but by having the specimens and pictures before me they could easily point each one out. Nor was I satisfied until I had submitted my drawings to other Indians, and proved by their giving the same names to each, that my first informant had told me correctly. The allegorical meaning, however, will require for determination time and careful study. Indians are very peculiar in giving information relative to their myths and allegories. Even when one is well acquainted with them and has their confidence, much caution is required, and it is useless to attempt to obtain any reliable information unless they are in the humor of imparting it.

I have observed another peculiarity among the Haidahs. They do not seem to have any particular standard style of drawing their figures; consequently, unless a person is familiar enough with the general idea to be conveyed, it would be difficult to determine the meaning either of a carving or drawing, unless the Indian was present to explain what he intended to represent. For instance, Figs. 6 and 16 are drawn by two different Indians, and both represent the frog. The bear, beaver, and Wasko or wolf, are different in the carvings from the tattoo designs, and so of other tattoo figures. Still, there are certain peculiarities which, once known, will enable one readily to determine what the correct meaning is. I have even known the Indians themselves to be at a loss to tell the meaning of a design. I will cite one instance illustrative of this. One of the Haidahs brought me a bone which he had rudely carved to resemble an animal; I pronounced it without hesitation to be a lizard. He said he would leave it with me till the next day, and would then tell me what it was. I showed it to several Indians in the mean time, and they thought as I did, that it was a lizard or newt. Any person on the Atlantic coast would have pronounced it an alligator. After we had exhausted our guessing, the Indian who carved it said it was an otter, and pointed to its teeth which were the only distinguishing features to prove that it was not a lizard or a crocodile.

The carvings of the pillars are thought by many persons to resemble Chinese or

Japanese work, and in order to satisfy myself upon that point, I showed the carvings to a party of very intelligent Japanese who visited Port Townsend several months since. They examined them carefully and critically, and pronounced them entirely unlike anything they had ever seen in their own country. In fact, they seemed as much interested with the specimens as our own people. I have seen similar carvings by the natives of the Feejee Islands, but on the northwest coast they are confined almost exclusively to the Haidahs on Queen Charlotte's Island, and to the Chimseans on the mainland. The carvings I particularly allude to are those representing several figures one above the other, as shown by the sketches and photographs of the carved posts or pillars placed before the entrances to their houses.

The limited time the Haidahs were at Port Townsend did not enable me to ascertain the origin of this system of carving, or of their custom of tattooing their bodies; what little information I did obtain was given with evident reluctance; but, as we became more acquainted and they began to understand what my object was in obtaining information, they became more communicative, and promised me that this present summer (1874) they would again be here and would bring more carvings and would give me all the information I wished.

Plate No. 2, fig. 8, shows a tattoo design of a halibut, and a painting on a buckskin cape representing the thunder bird of the Sitka Indians, worn by a medicine man during his incantations.

The belief in the thunder bird is common with all the tribes of the northwest coast, and is pictured by each tribe according to their fancy. I have traced this allegory from the Chenooks, at the mouth of the Columbia, through all the coast tribes to Sitka. The general idea is the same throughout; it is a belief in a supernatural being of gigantic stature, who resides in the mountains and has a human form. When he wishes for food he covers himself with wings and feathers as one would put on a cloak. Thus accoutred, he sails forth in search of prey. His body is of such enormous size that it darkens the heavens, and the rustling of his wings produces thunder.

The lightning is produced by a fish, like the *Hypocampus*, which he gets from the ocean and hides among his feathers. When he sees a whale he darts one of these animals down with great velocity, and the lightning is produced by the creature's tongue, which is supposed to be like that of the serpent. This is the general idea of the mythological legend, slightly altered in the narrative by different tribes and differently depicted by various painters.

The Haidahs seem to have the greatest variety of designs, and they seem to be the principal tribe who tattoo themselves to any extent. Where they acquired the practice or from whom it was learned, it will be difficult to determine. This is an interesting ethnological question, and worthy of further investigation.

Among other customs of the Haidahs which I observed is the practice of gambling, which is common among all the North American Indians.

In my paper on the Indians of Cape Flattery, published by the Smithsonian Institution (No. 220), I have given an account of the gambling implements of the Makahs, which consist of circular disks of wood, highly polished and marked on

the edges to designate their value. The Haidahs, instead of disks, use sticks or pieces of wood four or five inches long, and a quarter of an inch thick. These sticks are rounded and beautifully polished. They are made of yew, and each stick has some designating mark upon it. There is one stick entirely colored and one entirely plain. Each player will have a bunch of forty or fifty of these sticks, and each will select either of the plain sticks as his favorite, just as in backgammon or checkers the players select the black or white pieces. The Indian about to play, takes up a handful of these sticks, and, putting them under a quantity of finely-separated cedar bark, which is as fine as tow and kept constantly near him, he divides the pins into two parcels which he wraps up in the bark and passes them rapidly from hand to hand under the tow, and finally moves them round on the ground or mat on which the players are always seated, still wrapped in the fine bark, but not covered by the tow. His opponent watches every move that is made from the very first with the eagerness of a cat, and finally, by a motion of his finger, indicates which of the parcels the winning stick is in. The player, upon such indication, shakes the sticks out of the bark, and with much display and skill throws them one by one into the space between the players till the piece wanted is reached, or else, if it is not there, to show that the game is his. The winner takes one or more sticks from his opponent's pile, and the game is decided when one wins all the sticks of the other.

As neither of the players can see the assortment of the sticks, the game is as fair for one as the other, and is as simple in reality as "odd or even" or any child's game. But the ceremony of manipulation and sorting the sticks under the bark tow gives the game an appearance of as much real importance as some of the skillful combinations of white gamblers.

The tribes north of Vancouver's Island, so far as my observation has extended, use this style of sticks in gambling, while the Selish or Flat-heads use the disks. Some persons have termed this game Odd and Even, and others have designated it Jack Straws; but the game as played by the Haidahs is as I have described it.

Kitkūn, the chief whom I have alluded to, came to my office one day with one of his tribe, and took quite an interest in explaining the game. The two men played slowly at first, the Chief explaining as the game proceeded, till finally they played with their usual earnestness and rapidity, and I found that the game, with its accompaniment of singing and beating time, was quite as exciting and as interesting as any Indian game I ever witnessed. Sometimes the game is played between only two persons, at other times a dozen may be seen seated on each side, particularly when different bands meet. Then the excitement is intense, and the game is kept up day and night without intermission, and some Indians lose everything they possess, and come out of the play stark naked and remain in a state of nudity till some friend gives them a blanket or an old shirt.

It is probable that the Haidahs have other gambling games, but I have seen only this kind, and the game which Kitkūn explained to me was played with a bunch of sticks which I obtained in Sitka, showing that the northern tribes have the same game with sticks, in common, as the Selish or Flat-head Indian tribes have a common game with disks.

The Haidah Indians have another custom which I have not observed among any of the tribes of the northwest coast, with the exception of these people. It is the practice of cremation or burning the bodies of any of their friends who may die while absent from their homes. An instance of this kind came under my observation at Port Townsend, W. T., on Sunday, March 29th, 1874. A large party of men, women, and children, numbering about one hundred and fifty persons, had been encamped for a couple of weeks on the beach. One of the men who had been at work at the saw-mill in Port Discovery, some seven or eight miles distant from Port Townsend, had died there, and his body had been brought around to Port Townsend. On the morning of the day named, the party broke up their camp and moved in slow procession in six large canoes to Point Wilson, near Port Townsend, where a pile of drift logs was formed into a sort of altar and the body placed upon it, and the whole reduced to ashes; the women singing their death songs, amid howlings, beating of tambourines, and other savage displays. When the whole was burned, one old woman gathered the charred bones and placed them in a box, and the whole party left for Victoria, British Columbia, on their way home to Queen Charlotte's Islands.

I asked one of the Indians why they burned the body. He replied that if they buried it in a strange land their enemies would dig it up and make charms with it to destroy the Haidah tribe. This is the only instance of the kind which has come under my own immediate observation, but I have been informed by other persons that they have observed the same practice on other occasions, but I am not prepared to say whether cremation is a general custom among the Haidahs, or only confined to particular cases like the one I have described.

The Haidahs are one of the most interesting tribes I have met with on the northwest coast. Their insular position and the marked difference in their manners and customs from the Indians of the mainland give me reason to think that very interesting and valuable results in ethnology can be had by a thorough investigation among the villages on the islands. Their carved images, their manufactures in wood and stone, and in silver ornaments, and other evidences of their present skill, and the rich stores of material of a former age to be found in the shell heap remains, are matters well worthy of the careful consideration of those who desire to make up a history of the coast tribes of the northwest. British Columbia is, as it were, sandwiched between Alaska and Washington Territory, and a description of the coast Indians from the Columbia River to the Siberian borders, cannot be complete without including the Indians of Vancouver's Island, Queen Charlotte's Islands, and the adjacent mainland.

I am of the opinion that it will be found more economical and attended with better and more satisfactory results, to have such investigations pursued by persons resident on the northwest coast, rather than to entrust them to the very limited visits of scientific expeditions. Investigations of this kind require time and careful study before correct results can be arrived at.

A knowledge of the habits, manners, and customs of the natives, and a general understanding of the language, is of the first importance. The person making the investigation should be his own interpreter, and these requisites can be

attained only by a long residence and observation among these Indians. The impressions of casual travellers are not always reliable, nor are the interpreters who generally accompany scientific expeditions always capable of understanding correctly what they are required to translate.

It is interesting to read the reports and observations of the early voyages of Cook, La Perouse, Portlock and Dixon, Marchand, and others who have visited Queen Charlotte's Island, and see how little they really knew or understood about these natives.

The best account that I have seen, and that is but a meagre one, is in Marchand's Voyage Round the World, performed during the years 1770 '71, '72, in the "Solide," a ship fitted out in France for the purpose of trading on the Northwest coast of America. But Marchand and all the other early voyagers labored under a very great difficulty; they did not understand the language of the natives, and their only means of intercourse was by signs. Hence we find the accounts of the voyages of every nation, Spanish, Portuguese, French, and English, full of theories, and scarce any two alike. When the narrators confine themselves to descriptions of things which they saw, such as the dwellings, carvings, canoes, and other manufactures, and the usual appearance of the natives, their accounts generally agree; but when they commence to form hypotheses on imaginary meanings of the things they saw, they are lamentably at fault.

The following description of a house at Cloak Bay, on North Island, the most northerly island of the group, gives a general idea of a Haidah house of the present day. I quote from Marchand:—

"The form of these habitations is that of a regular parallelogram, from forty-five to fifty feet in front, by thirty-five in depth. Six, eight, or ten posts, cut and planted in the ground on each front, form the enclosure of a habitation, and are fastened together by planks ten inches in width, by three or four in thickness, which are solidly joined to the posts by tenons and mortises; the enclosures, six or seven feet high, are surmounted by a roof, a little sloped, the summit of which is raised from ten to twelve feet above the ground. These enclosures and the roofing are faced with planks, each of which is about two feet wide. In the middle of the roof is made a large square opening, which affords, at once, both entrance to the light, and issue to the smoke. There are also a few small windows open on the sides. These houses have two stories, although one only is visible, the second is under ground, or rather its upper part or ceiling is even with the surface of the place in which the posts are driven. It consists of a cellar about five feet in depth, dug in the inside of the habitation, at the distance of six feet from the walls throughout the whole of the circumference. The descent to it is by three or four steps made in the platform of earth which is reserved between the foundations of the walls and the cellar; and these steps of earth well beaten, are cased with planks which prevent the soil from falling in. Beams laid across, and covered with thick planks, form the upper floor of this subterraneous story, which preserves from moisture the upper story, whose floor is on a level with the ground. This cellar is the winter habitation."

The entrance door of their edifices is thus described:—

“This door, the threshold of which is about a foot and a half above the ground, is of an elliptical figure; the great diameter, which is given by the height of the opening, is not more than three feet, and the small diameter, or the breadth, is not more than two. This opening is made in the thickness of a large trunk of a tree which rises perpendicularly in the middle of one of the fronts of the habitation, and occupies the whole of its height; it imitates the form of a gaping human mouth, or rather that of a beast, and it is surmounted by a hooked nose about two feet in length proportioned in point of size to the monstrous face to which it belongs. \* \* \* \* Over the door is the figure of a man carved, in a crouching attitude, and above this figure rises a gigantic statue of a man erect, which terminates the sculpture and the decoration of the portal. The head of this statue is dressed with a cap in the form of a sugar-loaf, the height of which is almost equal to that of the figure itself. On the parts of the surface which are not occupied by the capital subjects, are interspersed carved figures of frogs or toads, lizards, and other animals.”

This description by Marquand is that of the houses of the present inhabitants. The hooked nose mentioned is the *Skamsquin* or *eagle*; and the sugar-loaf hat is the *Tadn skillik*.

If Marquand had been able to procure the services of a skilled interpreter, he and his officers could have ascertained the true meaning of these emblems as easily as I have done; but not being able to exchange ideas with the natives, they came to their conclusions, and framed their theories by a series of guesses; and as all the early explorers formed their theories of the Indians upon the same lucid basis, it is not to be wondered at that so much of error has found place in all their narratives. It is, however, a source of surprise, that, since the time of those old voyagers, a lapse of nearly a century, no one has attempted to give a description of those islanders, or to explain the simple meaning of their devices. The Queen Charlotte's group presents to-day as fresh a field for the ethnologist and archæologist as if no explorers had ever set foot upon their shores.

Of the extent and nature of these carvings, Marquand adds:—

“These works of sculpture cannot undoubtedly be compared in any respect to the master-pieces of ancient Greece and Rome. But can we avoid being astonished to find them so numerous on an island which is not, perhaps, more than six leagues in circumference, where population is not extensive, and among a nation of hunters?” The writer was alluding to North Island, one of the smallest of the group; and when it is remembered that in every village on every one of the islands of the group these sculptures are quite as abundant, some idea can be formed of the number to be seen on Queen Charlotte's Islands. “Is not our astonishment increased,” adds Marquand, “when we consider the progress these people have made in architecture? What instinct, or, rather, what genius, it has required to conceive and execute solidly, without the knowledge of the succors by which mechanism makes up for the weakness of the improved man, those edifices, those heavy frames of buildings of fifty feet in extent by eleven in elevation! Men who choose not to be astonished at anything will say, the beaver also builds his house; yes, but he does not adorn it; nature, however, has given the beaver the instru-

ment necessary for building it; she has certainly placed the man of the forest in the middle of the materials with which to construct his; but he has been under the necessity of creating the varying tools without which he could not employ those materials. A sharp stone, hafted on a branch of a tree, the bone of a quadruped, the bone of one fish, and the rough skin of another, form instruments more fit to exercise patience than to help industry, and which would have been ineffectual in seconding his efforts, if fire which he discovered, and the action of which he learnt to regulate and direct, had not come to the assistance of his genius, and of the art which he executes through the impulse of genius."

When we examine the whole of the operations necessary for constructing and ornamenting one of the edifices which I have just described, when we reflect on this assemblage of useful arts, and of those which are merely agreeable, we are forced to acknowledge that these arts have not taken birth on the small islands where they are cultivated; they come from a greater distance.

Marquand observes that "the distinction between the winter and summer habitations of the Queen Charlotte Islanders, recalls to mind the custom of the Kamtschadales, who have their *balagans* for summer and their *jourts* for winter; the former erected on posts or pillars, twelve or thirteen feet in height, and the latter dug in the ground and covered with a roof: it is even remarked that some of the *balagans* have oval doors."

The country of these Kamtschadales, as we know, is a peninsula of north-eastern Asia, and seems to show that this style of houses of northern Asia must have been introduced by immigration at some remote period from that region. In fact everything seems to prove that Asia peopled the northwest coast of America, the buildings, the manners and customs and general appearance of the natives from Vancouver's Island to the Siberian Coast, are very similar, and in certain respects nearly identical.

Marquand thinks, and my own observations certainly verify the theory, "that it is not without the sphere of probability, that the northwest coast should reckon three species of inhabitants; of the first date, the men who might belong originally to the very soil of America, if we adopt the opinion, that this large country had its own men or aborigines, as it has its animals and its plants," a view which is coincided in by Sir Charles Lyell, Agassiz, Forshey, Morton, Squire, and other eminent authorities. This first class of inhabitants I have in this paper termed Selish, or Flat Heads.

The second species are the Asiatics of the north, whose transmigration seems to have been retarded at Queen Charlotte's Islands, and to have stopped at Vancouver's Island; and lastly, and of the third date, the Mexicans, who fled for refuge to the coast after the destruction of their empire, and who peopled the Californias, and wandered north and mingled with the Selish. Marquand says, "that everywhere on the Queen Charlotte's Islands appear the traces of an ancient civilization; everything indicates that the men with whom they had the opportunity of being acquainted have belonged to a great people, who were fond of the agreeable arts, and knew how to multiply the productions of them."

I feel a great confidence that in the shell heap remains to be found on those islands, as well as in the caves and the mausoleums of the dead, may be discovered relics of antiquity which will well repay the archæologist for exploring them; and that on these islands may be discovered those evidences which will form the missing link in the chain of testimony which will add to the history of the origin of the North American Indians, and perhaps enable us to trace with greater certainty those ancient annals which are now hidden in mist and obscurity, and only darkly hinted at in the shadowy legends and mythological lore crooned over by the ancient men and women, and handed down to after generations, who add to every fresh recital an additional sprinkling of the dust of obscurity.

I have already, in my former writings on the Indians of the northwest coast,<sup>1</sup> alluded to the Mexican terminal *tl*, as occurring in the vocabularies of the Chinooks, Chihalis, Quenáíült, and Makah Indians of the west coast of Washington Territory, a fact noticed by Anderson—who compiled the vocabulary of the Nootkan language, which is in the Journal of Cook's Third Voyage, and in that of Marquand and others. A reference to my vocabulary of the Makah Indians (Smithsonian Contributions to Knowledge, 220) will show it to be rich in words having that terminal. Hence the supposition that while the Selish retained their identity as separate and distinct from the Asiatic tribes, they did receive an influx from the hordes of Mexico, and from them obtained words which have become engrafted into their language during a lapse of centuries, just as we can now perceive the use of English words already among those Coast Indians, who for many years have had intercourse with the traders of the Hudson's Bay Company, and the use of certain Russian words among the natives of Alaska, from their intercourse with the traders of the Russian American Fur Company.

But the vocabularies of the early voyagers are not correct. No two of them are alike, a fact which is to be attributed, in part, to there being at that time no recognized standard for spelling Indian words, and in part to the difficulty of understanding the natives. I will illustrate this by a remarkable error. The word Nootka, as it is usually spelled, or Nütka, as it should be spelled, is not the name of a place or a people; and it is surprising to me how the intelligent persons who, for so long a time, made "Nootka" their head-quarters, and named the tribe Nootka Indians, and even the authors of the treaty (the Nootkan Treaty), between Great Britain and Spain, should not have discovered the error.

The mistake arose in this way. The Indians have a custom of forming a ring, taking hold of each other's hands, and running or dancing in a circle. This is termed "*Nootka*," and was explained to me by a Clioquot Indian who resides near Nootka, and who could speak English. He said, if you run round your house, or round a canoe, or dance round in a circle, we say "*Nootka*;" and he remarked that, probably the Indians were dancing on the beach at the time the ethnologist of Cook's Expedition was asking the name of the country, or the people; and the Indian, thinking he asked what the people were doing on the beach, said NOOTKA,

---

<sup>1</sup> "The Northwest Coast, or Three Years in Washington Territory," Harper & Bros., 1857; and "The Indians of Cape Flattery," Smithsonian Institution (220).

and the white people having called the place and people Nootka, the Indians took no pains to undeceive them. This is very common for Indians to do, even with their own names, or the names of their friends. If a stranger, and particularly a white man, makes a mistake in pronouncing or applying an Indian name, they think it a good joke, and wish to perpetuate it. For instance, a white man asked an Indian, "what is your name?" He replied, "*Halo*," which means, I have none. The man thought that was the Indian's name, and always called him Halo. The tribe liked the joke, and to this day this Indian is known among the whites as Halo, and is so called by his tribe.

Numberless instances could be adduced to show this very common custom of the coast Indians, to take no pains to correct mistakes in language, but to consider such errors as good jokes which are to be kept in perpetuity.

This illustration will serve to show how easy and natural it was for the white man to make the mistake; and how very natural it was for the Indians to keep up the error with every succeeding party of white men who visited them. They thought if Captain Cook called the place Nootka, it must be so, whether the Indians called it so or not. The correct name of the place is Mōwachat, or Bowatchat, which means, the place of the deer, from Bōkwitch, a deer, which word has been changed in the Jargon to Mowitch, a deer. Since the white men have called the place for so many years Nootka, the Indians speak of it to a white man under that name, just as they speak of the towns which have been settled by the whites, as Victoria, or Port Townsend, or Dungeness, but among themselves they invariably call the place and people by their Indian names, and the Nootkans always laugh at the mistake the white man made in naming them and their country after a dance.

I will not, at this time, press further this discussion upon a subject which to perfectly understand will need extended observations to be made upon the spot, and would require an explanation that would carry me beyond the limits to which I purpose to confine myself in this present paper. I trust that it will be sufficient for me to have shown that the subject of the carvings in wood and stone and precious metals, the paintings and tattoo marks of the Haidahs, is one of very great interest, and one which not only never has been properly explained, but never properly understood.

When we reflect on the great number of centuries during which all knowledge of the interior of the Pyramids of Egypt was hidden from the world, until the researches of Belzoni discovered their secret treasures, and until Champollion, by aid of the Rosetta stone, was enabled to decipher their hieroglyphical writings, may we not hope that the knowledge of the ancient history of the natives of the northwest coast, which has so long been an enigma, may be traced out by means of the explanation of the meaning of the symbols such as I have been enabled to discover in part, and have in this paper described?

This very brief memoir, made during the visit of a party of Haidah Indians for a few weeks in Port Townsend, will serve to show what could be effected if the Government would empower some person here, and appropriate sufficient funds to be expended in these ethnological and archæological researches.

Port Townsend is a place peculiarly adapted to the prosecution of these investigations. Its near proximity to Victoria, where hundreds, and sometimes thousands of the northern Indians congregate every spring for purposes of trade, will enable the observer to collect rich stores of material, in addition to what may be obtained here by the same Indians when they visit Puget Sound.

These Indians, heretofore, have disposed of all their curiosities and other products in Victoria before coming to the American side. But I am of the opinion that hereafter they will bring their wares to Port Townsend, having found by the experience of the past summer that they can dispose of all their manufactures here. During the past summer we have had Indians in Port Townsend from Kwe-nai-ült, Kwillehuyte, and Cape Flattery, on the American coast, and from Nittinat, Clyoquot, Nootka, and other tribes on the west coast of Vancouver's Island, as well as the Haidahs, Chimseans, and other tribes north of Vancouver's Island as far as Sitka. A steamship leaves Puget Sound once every month for Sitka, and the United States Revenue vessels of this district make frequent excursions as far north as Behring's Strait. Arrangements could undoubtedly be made by which an authorized person could have conveyance to any point north that it might be desirable to visit, and could remain as long as required.

The field of observation on the northwest coast is very extensive, and cannot be exhausted for many years. It is a field that would yield such rich returns to ethnology, as well as to every other branch of natural science, as would amply repay any outlay that the Government might make. The history of the coast tribes is becoming of more importance every year, and a connected description of the Aleuts and other coast tribes of Alaska, the tribes of Western British Columbia, Washington, and Oregon would not only be interesting, but would be valuable in assisting to solve that perplexing question of the origin of the North American Indian.

# CARVINGS AND DESIGNS OF HAIDAH INDIANS.

Plate 1.

STONE CARVINGS.  
No 1a.

Carvings by Haidah Indians of Queen Charlotte's Islands, British Columbia, representing the carved posts set up in front of their Lodges showing the Totems or heraldic design, of the families occupying the house. Descriptions given by Tit-kaut, Chief of the Taskeek village, Geneskelas, a brother of Kit-kau & Capt. Skedance, Chief of the Noona Village, east coast of Horesby's Island.  
Drawn by J.G.Swan, Port Townsend, W.T. May 1873.

No 1. CARVINGS AND DESIGNS OF HAIDAH INDIANS.

WOOD CARVINGS.

**Hoorts**  
*(The Bear.)*

**Tadn skillik**  
*hat worn by Chiefs.*

## ADVERTISEMENT.

---

At the commencement of the operations of the Smithsonian Institution a system of meteorology was established, carried on by voluntary observers, which was continued for more than twenty years until it was transferred to the Signal Service of the United States Army in 1874 to be continued by means of the annual appropriations of Congress. This system included observations on the temperature, pressure, aqueous precipitation, moisture of the air, and winds.

The object now of the Smithsonian Institution is to render the results of these observations accessible to meteorologists by their reduction, discussion, and publication; but to give greater value to this work it has been thought advisable to incorporate in it all accessible and reliable meteorological observations that have been made in the United States since the early settlement of this country.

The first part of the general work, that on the aqueous precipitation, was published in 1872, that which relates to the winds is now in the press, and the other parts will follow in succession.

The present memoir relating to the temperatures contains the results of all observations to the end of the year 1870, from the following sources:—

1st. The registers of the Smithsonian Institution, embracing upwards of 300 folio volumes.

2d. The joint publications of the Institution and of the Patent Office and Department of Agriculture.

3d. All the publications and unpublished records of the meteorological system of the United States Army.

4th. The records of the United States Lake Survey under the Engineer Department of the United States Army.

5th. The records of the United States Coast Survey, under the Treasury Department.

6th. The volumes compiled by Dr. F. B. Hough from observations made under the direction of the Regents of the University of the State of New York.

7th. The records made in Pennsylvania under the direction of the Franklin Institute of Philadelphia.

8th. The transactions of various societies and periodical publications.

The first part of the work was the formation of an extended series of classified tables derived from the foregoing sources, and the second the deduction from these consolidated tables, of average temperatures. The first of these series, owing to its great bulk, must for the present remain in manuscript. It can, however, be

consulted at any time at the Institution. The second series, which is given in the following pages, consisting of average temperatures, is sufficient to furnish all necessary information for the study of our climate as far as it depends upon temperature.

All the materials were placed in charge of Mr. Charles A. Schott, Assistant United States Coast Survey, to be reduced and discussed under his direction by trained computers, at the expense of the income of the Smithsonian fund. He was ably assisted by Mr. E. H. Courtenay, of the United States Coast Survey.

The character of Mr. Schott for scientific knowledge, sagacity, and skill in the line of investigation, and scrupulous accuracy as exhibited in the previous meteorological publications of the Institution, give assurance that the work here presented to the public is a valuable contribution to the knowledge of the climate of the United States.

JOSEPH HENRY,  
*Secretary Smithsonian Institution.*

WASHINGTON, D. C.,  
January, 1876.

## SECTION I.

### TABLES, DISTRIBUTION, AND VARIATIONS OF THE ATMOSPHERIC TEMPERATURE IN THE UNITED STATES,

AND SOME ADJACENT PARTS OF AMERICA.

#### GENERAL REMARKS.

THE laws of the distribution of winds, rain, and heat of a large portion of North America, embracing the normal or statical values as well as their variations with seasons and for longer periods of years, form part of those studies with whose results we are most directly concerned. Although this ground has been gone over many times and must continue to be cultivated, the continued accumulation of new materials enables the investigator gradually to present his results in a more precise form and to enter more fully into detail or local discussions. Whatever imperfections the available records may possess, their effect in the mean values will constantly diminish with the increase of reliable modern observations; moreover, they could not be dispensed with on account of inaccuracies, since they form the only material in our possession for the discussion of such subjects as possible changes in climate since the first settlement of the States. In the following work we shall therefore be chiefly occupied with the establishment of tabular results comparable among themselves, with obtaining mean or normal values or the so-called constants of temperature, as factors of the climate, and with the range of the fluctuations, daily, annual, and secular, also with the generalization of the results either in analytical or graphical form.

The advantages gained by an early discussion of observations beyond putting us in possession of results for immediate use are several; light is thrown on the reliability of the records, their sufficiency or insufficiency for our present or future wants, and the kind of results they are or are not capable of yielding, is indicated. Besides improvements in methods of observing and in instrumental means are likely to result, as well as incitements of the observer to renewed efforts.

Our earliest records of temperature, the results of which are given in the following tables, date about a quarter of a century after the invention of Fahrenheit's thermometer,<sup>1</sup> and with few exceptions all the observers in this country have made

---

<sup>1</sup> The following information is extracted from Gehler's *Physikalisches Wörterbuch*, Leipzig, 1839.

\* \* \* To Daniel G. Fahrenheit, of Dantzic (Prussia), is due the merit of having constructed,

use of his scale, in consequence of which all tabular quantities, and results presented in this paper have reference to this graduation. For the sake of uniformity, records originally given in Réaumur or Centigrade scale have been converted into that of Fahrenheit, and however advisable otherwise it might have been to adopt the Centigrade scale, such a step was forbidden by the great labor and consequent expense which the conversion would have entailed.

---

on proper principles, thermometers upon which reliance could be placed; his earlier instruments were filled with alcohol, but about the year 1714 he used mercury for this purpose. According to his own account, he recognized three principal points, viz. : his so-called absolute zero, representing the extreme cold experienced by him in the severe winter of 1709 and erroneously supposed to indicate the greatest cold, the freezing point of water, and a point representing the heat of the human body; in practice, however, he made use of the freezing point as well as of the boiling point of water, with the fixity of which latter he became acquainted in 1714. Supposing the volume of mercury at the temperature represented by his zero point to be 11124 parts, he noticed an expansion of 32 parts at the temperature of freezing water, and of 212 parts at the temperature of boiling water, and accordingly adopted the numbers 32 and 212 to indicate these temperatures. Before Fahrenheit's instruments came into general use, Réaumur brought out his spirit thermometers graduated between the freezing and boiling points of water from 0 to 80, and shortly after, Celsius, about 1742, introduced the Centigrade division between the same points. The spirit thermometers used in the preceding century had arbitrary scales, and were not generally directly comparable. \* \* \* Fahrenheit had already noticed the effect of a change in the atmospheric pressure on the position of the boiling point, but the proper allowance or reduction to a standard pressure was not satisfactorily ascertained in his time. It would seem that allowance was made for the expansion of the glass tube in the above-mentioned experiment, since the dilatation of mercury is nearly 0.0001 of its volume for 1° Fah. All of the thermometric scales mentioned are intended to measure equal increments of heat by equal increments in their scale readings, but for the purpose of comparison and discussion it is much to be desired that all should agree to use the same scale, the Centigrade scale being the one most likely to take the place of the others.

In connection with the cold indicated by the zero of Fahrenheit's scale it may be remarked as an *accidental* circumstance, that it may and has been taken *roughly* to be that of the mean annual temperature of the pole, hence the possibility of representing approximately the annual mean temperature in the latitude  $\phi$  by the simple expression  $81^{\circ}.5 \cos \phi$  *without* the addition of a constant.

TABULATION  
OF  
RESULTING MEAN TEMPERATURES

FROM  
OBSERVATIONS EXTENDING OVER A SERIES OF YEARS, FROM THE EARLIEST  
TO NEARLY THE PRESENT TIME,

FOR  
EACH MONTH, SEASON, AND THE YEAR,

PRINCIPALLY FOR  
STATIONS IN NORTH AMERICA.

## EXPLANATIONS AND REMARKS

ON THE

### CONSOLIDATED TABLES OF RESULTING MEAN TEMPERATURES FOR EACH MONTH, SEASON, AND THE YEAR.

---

THAT part of the tables which refers to the United States is arranged in alphabetical order according to states and territories, and the names in each subdivision are given alphabetically. For all stations beyond the limits of the United States it was considered more advantageous to adopt a geographical arrangement, but the alphabetical sequence of stations under each geographical district is preserved.

The tables contain: The number and name of each station, its latitude and longitude, its elevation above the sea when known, its mean temperatures for each month, each season, and for the whole year, the beginning and ending of the series of observations, its actual extent, the observing hours, the name of the observer with references.

The geographical positions are given to the nearest minute of arc, as far as known, the longitudes are counted as usual west of Greenwich. The positions which became known through the operations of the United States Coast Survey are reliable, as well as those given upon the authorities of the United States Lake Survey, officers of the United States Army, directors of astronomical observatories, and, in general, all those positions which have been determined by direct astronomical observations and those connected with the General Land Office. Positions given on the authority of the observer, and these are by far the most numerous, are less trustworthy, since most of these were taken from State or county maps having no adequate astronomical basis. The results for longitude depending on the electric telegraph are of so recent date that but few maps have as yet incorporated them. Although no pains have been spared to render these geographical positions as trustworthy as possible, they are, in general, when taken from maps evidently in the given latitudes affected with a probable uncertainty of from  $\pm 3'$  to  $\pm 5'$  and in the given longitudes with a probable uncertainty of from  $\pm 5'$  to  $\pm 8'$ . Fortunately for the immediate wants of the discussion of temperature a moderate approximation to the true position suffices. The elevations of the observing stations depend in all cases upon the statements of observers; these also no doubt require considerable improvement, as but few depend upon direct hypsometric measures or on measured differences of level from known railroad or

canal levels; those depending on barometric observations can only be regarded as rough approximations. Heights near tide-water may be considered to be reliable.

Unless otherwise stated, the mean tabular values of the temperature, always expressed in degrees of the Fahrenheit scale, refer to the *observing hours* noted, and are consequently uncorrected for daily variation. In all cases where the observing hours were variable or were changed during the series, the results were referred either to those observing hours maintained for the longest period or to those susceptible of the greater accuracy, or else all were corrected for daily fluctuation. The means for correcting observed values, taken at stated epochs of the day and for any month, were furnished by the discussion of the daily variation, but the stations available for such discussions are comparatively so very few in number, and are almost wanting for the western part of the United States, that but a small portion of our results could be so corrected. If we had better and more complete materials for daily variation, it would undoubtedly have been preferable to correct all tabular results for this inequality, but in their absence it was deemed advisable to attempt no more than to present the results *in any one series* for a *uniform set* of hours of observation, correcting as stated in all cases where the observer has changed his times of observation; this gives us the advantage of effecting hereafter a more satisfactory reduction to the mean of twenty-four hours whenever we come into possession of new and, it is to be hoped, automatic registers.

Respecting the results obtained under the University System of the State of New York, the daily mean was directed<sup>1</sup> to be found by adding to the morning observation twice the afternoon observation, and twice the evening observation to that of next morning, and dividing their sum by six. This may be symbolically expressed by  $\frac{1}{6}\{\odot_r + 3_a \text{ bis} + (\odot_s + 1^h) \text{ bis} + \odot_r\}$ ; the morning observation was to be taken a little before sunrise. The means given in the table were made out in accordance with this rule.<sup>2</sup>

With respect to the Smithsonian system of meteorological observations, the result of the three hours 7 A. M. 2 and 9 P. M. was found to approximate less closely to the true daily mean than the result obtained by adding twice the reading at 9 P. M. to the readings at 7 A. M. and 2 P. M. and dividing this sum by four. The latter rule was therefore adopted, and is symbolically indicated by  $\frac{1}{4}\{7_m + 2_a + 9_a \text{ bis}\}$ . In the column headed observing hours the symbols  $\odot_r$  and  $\odot_s$  stand for sunrise and sunset; the affixes m. and a. to any given hour indicate morning and afternoon respectively; N. and Mdt. stand for noon and midnight; M. and E. for morning and evening; Max. and Min. for mean from maximum and minimum readings;

<sup>1</sup> F. B. Hough, p. iv of the introduction to the results of meteorological observations made in obedience to instructions from the Regents of the University at sundry Academies in the State of New York, Albany, 1855.

<sup>2</sup> It should also be mentioned that for these Academy stations the monthly means are made up from the half-monthly means, there is therefore a slight inconsistency in the results for the months having an odd number of days (the first 15 days having been united into a mean for all months, excepting February). The October mean is most affected, less so May and March; the amount generally less than  $0^\circ.1$  is small enough to be neglected.

“bis” attached to any hour indicates that the reading at this hour received double weight as explained above.

Respecting the corrections necessary to refer monthly and annual means depending on observations at certain hours to what they would have been had the observations been made hourly and continued day and night, the reader is referred to the discussion of the daily variation of the temperature. In this discussion it is shown that the mean of hourly observations represents the average temperature of the day within about  $0^{\circ}.01$  Fah.

The following table of corrections for daily variation to means resulting from observations at certain hours was prepared directly from observations extending over a series of years at Toronto, Mohawk, New Haven, and Philadelphia; it is inserted here on account of its frequent application to our tabular results, either to refer them to the mean of the day or to a uniform set of hours, in which latter case the table can be made readily to apply. This table of corrections was found to answer well enough for the Eastern and Western States lying within the range of latitudes of the four stations; for Southern States and for the elevated western portion of the United States other less reliable corrections had to be supplied.

Table of corrections for daily variation of temperature, derived from observations made at Toronto, Mohawk, New Haven, and Philadelphia; for every hour and for various combinations of hours, in degrees of Fahrenheit.

<sup>1</sup> Observations in "morning and evening," from October, 1796, to May, 1802, and from July, 1816, to June, 1821; from September, 1841, to June, 1845, at 10<sub>m</sub> and 10<sub>e</sub>. <sup>2</sup> Value for August interpolated. <sup>3</sup> Observations made every four hours. <sup>4</sup> Fort McPherson.

<sup>5</sup> From 6 to 12 observations daily.

<sup>6</sup> Fort Hope.

<sup>7</sup> Fort Hope. The September and October observations, made at 8<sub>m</sub> 8<sub>e</sub>, have been referred to 8<sub>m</sub> 2 8<sub>e</sub> by means of the "Boothia Felix" table. Correction to scale at -35° = -4°.5; at 0° correction supposed 0, and a proportional amount between 0° and -35° applied.

<sup>8</sup> Observations made at daylight, warmest time of day, and after dark.

<sup>9</sup> Corrected for daily variation by means of Dove's Toronto Table.

<sup>10</sup> The means for 1825-6 are derived from the daily extremes, those for 1838-39 from observations at 8<sub>m</sub> 8<sub>a</sub>. They have been corrected for daily variation by means of the Toronto formula.

<sup>1</sup> Observations for 1853-54, at 7<sub>m</sub> 2, 9<sub>a</sub>.

<sup>2</sup> Results from three observations daily, at hours not stated.

<sup>3</sup> At the even hours. The values for 2<sub>m</sub> and 4<sub>m</sub> were interpolated from the readings at midn't and 6<sub>m</sub>, and by means of a minimum thermometer.

<sup>4</sup> Corrected for daily variation by means of the general table.

<sup>5</sup> At the Barracks, R. A., opposite Montreal. During the first year, the observations were made bi-hourly, at the *even* hours; during the second, bi-hourly, at the *odd* hours.

<sup>6</sup> Cape Diamond.

<sup>7</sup> Hours of observation 6<sub>m</sub> 9<sub>a</sub> N. 3<sub>a</sub> 6<sub>a</sub> 9<sub>a</sub>.—Captain Lefroy, in the “Canadian Journal” for November, 1852, notes a diminution of 2°.5 in the mean annual temperature, resulting from the last five years of this series, when compared with that for the first four years. It appears to be due to a change in the hours of observation.

<sup>8</sup> Observations for 4 years 6 months of this series were made at 6<sub>m</sub> 2<sub>a</sub> 10<sub>a</sub>. They were referred to 7<sub>m</sub> 2<sub>a</sub> 9<sub>a</sub> by means of the general table.

<sup>9</sup> Observations for the first five months at “Hatley,” a few miles to the southwest of “Sherbrook.”

<sup>1</sup> Near Niagara Falls. This series has been formed by combining the observations at "Clifton" with those at "Suspension Bridge, N. Y." They were made at various hours, and have been corrected for daily variation by means of the general table.

<sup>2</sup> Corrected for daily variation by means of Dove's Toronto table.

<sup>3</sup> Value for June interpolated.

<sup>4</sup> "The readings were recorded regularly at 8<sub>m</sub> N. 5<sub>a</sub>. When the highest or lowest temperature for the day occurred at other periods it was registered."

<sup>5</sup> Magnetic and Meteorological Observatory, in the grounds of the University of Toronto. The hours of observation for 1840 are not known, but the results can differ little from the true mean of the day; from January, 1841, to June, 1842, the observations were taken bi-hourly; from July 1, 1842, to June 30, 1848, hourly. Afterwards, to the end of 1852, the observing hours were irregular; not less than six readings were taken daily, and some hourly and bi-hourly. From January, 1853, to the end of the series, the observations were taken regularly at 6<sub>m</sub> 8<sub>m</sub> 2<sub>a</sub> 4<sub>a</sub> 10<sub>a</sub> and M., "excepting on Sundays, Christmas day, and Good Friday, when the instruments were read at 6<sub>m</sub> 2<sub>a</sub> only. These latter readings, though recorded in the daily register, are not

included in the hourly means of the month." From 1841 to 1863, inclusive, the observations have been corrected for daily variation, but since the correction to the mean of any one month amounts, in maximo, to only about ±°.1, and for the year to but ±°.02, it has been omitted from 1864-1870. The duties of the observatory are carried on by the director, G. T. Kingston, A. M., assisted by Messrs. Walker, Menzies, Stewart, and Davidson.

6 Observations in 1867-68 at Fish River, or Bolivar, 5 miles N. W. of Bon Secour. 7 Observations in August, 1859, at Livingston, 5 miles to the S. 8 Observations in 1853 at 7m 2a 9a. No correction for change of hours has been applied. 9 Observations in 1867 at Fort Gaines some miles to the west. 10 Observations at various hours; they have been referred to the mean of the day, making use of the "Fort Morgan table." 11 Observations from January, 1868, to October, 1869, inclusive, "6 miles east of Havana;" and from November, 1869, to January, 1870, inclusive, "near Greensboro." All the stations are within a radius of a few miles, and have about the same elevation.

<sup>1</sup> University of Alabama.

<sup>2</sup> Formerly Fort Nicholas.

<sup>3</sup> "Observations in summer at 6<sub>m</sub> 6<sub>a</sub>; in winter as early as the thermometer could be read in the morning, and as late in the evening.—Dove's corrections for these hours at Toronto have been applied."

<sup>4</sup> Old style. The difference in the calendars is 12 days, but the Russians carrying their time eastward and we westward, one day must be subtracted, thus making our account 11 days nominally in advance of the Russian. The Observations for 1866-67, and probably for the other years of the series, were made 8<sub>m</sub> N. 8<sub>a</sub>.

<sup>5</sup> Corrected for daily variation.

<sup>6</sup> In Siberia.

<sup>7</sup> Old style. The observations were taken at the Magnetic and Meteorological Observatory on Japonski Island. From May, 1847, to March, 1849, and for 1862 they were made hourly; from June, 1849, to Dec. 1856, 17 observations were taken daily, hourly, from 6<sub>m</sub> to 10<sub>a</sub>; for the years 1857-1861, and 1863-64, 19 observations were taken each day, hourly, from 4<sub>m</sub> to 10<sub>a</sub>. The observing hours in 1867 not stated, but the corrections to them must be very small. The series has been corrected for daily variation by means of the Sitka table by Schott.

<sup>8</sup> In 1867-68 called "Camp McPherson."

<sup>9</sup> Formerly "Fort Breckenridge."

<sup>10</sup> Also called "Fort Tollgate."

<sup>1</sup> Observations of one series, two years and four months, at 7<sub>m</sub> 2<sub>a</sub> 9<sub>a</sub>, were referred to 6<sub>m</sub> N. 6<sub>a</sub> and combined with the other series.  
<sup>2</sup> Observations for one year and two months at 7<sub>m</sub> 2<sub>a</sub> 9<sub>a</sub>, referred to 7<sub>m</sub> 9<sub>m</sub> 3<sub>a</sub> 9<sub>a</sub>. <sup>3</sup> Observations previous to 1855 at 7<sub>m</sub> 2<sub>a</sub> 9<sub>a</sub>, referred to 7<sub>m</sub> 2<sub>a</sub> 9<sub>a</sub>.  
<sup>4</sup> Observations for four months in morning and evening; assumed to be at 7<sub>m</sub> 2<sub>a</sub> and 7<sub>m</sub> 9<sub>m</sub>, and referred to 7<sub>m</sub> 2<sub>a</sub> 9<sub>a</sub> bis.  
<sup>5</sup> Observations for four years and one month at 7<sub>m</sub> 2<sub>a</sub> 9<sub>a</sub>, referred to 7<sub>m</sub> 2<sub>a</sub> 9<sub>a</sub> bis.  
<sup>6</sup> Observations prior to 1855 at 7<sub>m</sub> 2<sub>a</sub> 9<sub>a</sub>; a correction was applied, making use of the Key West Table, to refer them to 7<sub>m</sub> 2<sub>a</sub> 9<sub>a</sub>. The annual mean is not affected by this change of hours.

<sup>1</sup> Observations from January, 1861, to May, 1862, were made at Fort Wise or old Fort Lyon, some miles to the southeast of the present fort.

<sup>2</sup> The observations were made six miles S. of Farmington.

<sup>3</sup> The observations are stated to have been made in Windham Co. as indicated by the given position and height, but perhaps a mistake of 1° in Long. has been made.

<sup>4</sup> The observations were made at variable hours, the means being corrected for daily variation.

<sup>5</sup> There were from three to seventeen observations daily, between 6<sub>m</sub> and 10<sub>a</sub>; corrected for daily variation by means of the New Haven Table. Thermometer tested.

<sup>6</sup> Observations prior to August, 1867, at Fort Berthold, a few miles to the southwest.

<sup>7</sup> Also called "Greenwood." Observations in 1862, at Yankton, to the east.

<sup>1</sup> Observations in 1854, at O, 9m 3a 9a; they were referred to 7m 2a 9a by means of the general table. The observations of 1866 and 1867 were combined with those made at Delaware City.

<sup>2</sup> The observations have been corrected for daily variation. The series is much broken and many of the monthly means are imperfect, so that the results afford only a tolerable approximation to the truth. <sup>3</sup> Corrected for daily variation by means of the general table.

<sup>4</sup> The observations were made bi-hourly, at o.2<sup>b</sup> A. M., 2.2<sup>b</sup> A. M., and so on.

<sup>5</sup> The observations were made tri-hourly at Mid., 3 A. M., 6 A. M., and so on.

<sup>6</sup> Also called Atsuna Ofie.

7 The first seven years of this series were observed at Cantonment Clinch, three miles from Pensacola and fourteen miles from Fort Barrancas.

8 The observations were made at Fort Lauderdale from Jan. to Sept. 1839, and from July to Sept. 1840. This post is a few miles N. of Fort Dallas and the same distance from the sea.

9 The observations composing this series were made at Fort Marion and St. Augustine; principally at Fort Marion.

10 The observations composing this series were made at Forts Russell, Harley, and Wheelock, the same position being given for all.

FLORIDA.—Continued.

<sup>1</sup> The results previous to 1854 are defective on account of frequent blanks in the record. In 1856 and 1859 the observations were made at Thomaston, about three miles N. E. of The Rock.

<sup>2</sup> Old Fort Hall.

<sup>3</sup> Observations assumed to have been taken at or in the vicinity of the Fort.

<sup>4</sup> Also called Rochelle.

<sup>5</sup> Observations previous to 1866 were made at Edgington, about one mile to the west of Andalusia.

<sup>5</sup> In 1868, the observations were made two miles southwest, and afterwards two miles east of Brookhaven.

<sup>6</sup> Also called Fellowship.

<sup>7</sup> The temperature recorded at 6 P. M., is probably too high, being nearly as high as at noon.

MISSOURI.

6 Observations for 1867 at "Blackbird Hills," a few miles to the southwest of the mission. 7 Also known as "Elkhorn City."  
 8 Nason gives altitude 125 feet above river bed. 9 Also called Tamworth.  
 10 This series is composed of observations at Great Falls by H. E. Sawyer, and at Salmon Falls, about two miles southeast of Great Falls, by G. B. Sawyer.  
 11 Observations from January, 1835, to December, 1837, probably included in preceding series.

## NEW HAMPSHIRE.—Continued.

<sup>1</sup> This series is composed of observations at Littleton, by R. C. Whiting, and at North Littleton, about one mile north of Littleton, by R. Smith.

<sup>2</sup> The observing hours were  $\odot$ , 2<sub>s</sub>. The observations were corrected for daily variation by means of the general table.

<sup>3</sup> Also called *Barnstead*.

<sup>4</sup> Observations corrected for daily variation by means of the general table.

<sup>6</sup> The observations in March, 1849, were made at Belleville, about three miles northeast of Bloomfield.

<sup>6</sup> The observations composing this series were made at Branchburg Township, Mechanicsville, and Beadington, all within a radius of about three miles.

<sup>7</sup> The observations previous to 1865 were made at the junction of the Delaware and Rancocus Rivers, about four miles northwest of Chester.

<sup>8</sup> Observations corrected for daily variation by means of the general table.

NEW MEXICO.

Table with columns: NAME OF STATION, Lat., Long., Height, Jan., Feb., March, April, May, June, July, August, Sept., Oct., Nov., Dec. Rows include stations like Abiquin, Albuquerque, Camp Cimarron, etc.

NEW YORK.

Table with columns: Station Name, Lat., Long., Height, Jan., Feb., March, April, May, June, July, August, Sept., Oct., Nov., Dec. Rows include stations like Adirondack, Albany, Auburn, etc.

1 Observations for four years, Sept. 1849, to Dec. 1854, at O, 9m 3a 9a; they were referred to 7m 2a 9a. 2 Observations for May and June, 1850, at Taos. For seven months of the series, the observing hours were O, 9m 3a 9a; a correction was applied to refer them to 7m 2a 9a. 3 Observations for nine months of 1854, at O, 9m 3a 9a; referred to 7m 2a 9a. 4 Also known as Fort Lyon. 5 Observations prior to 1855, at O, 9m 3a 9a; referred to 7m 2a 9a. 6 From January, 1855, to September, 1867, inclusive, the observations were made at Fort Marcy, about one mile from Santa Fé. Previous to 1855, the observing hours were O, 9m 3a 9a; they have been referred to 7m 2a 9a.

7 Daily means computed by the formula  $\frac{a + 2b + 2c + a'}{6}$  where *a* represents an observation a little before sunrise, *b* one at 3<sub>a</sub>, *c* one at one hour after sunset, and *a'* the morning observation on the following day. The results thus obtained appear, on the average, to be about 0°.5 too high.

8 Corrected for daily variation by means of the general table.

9 Observations at 9<sub>m</sub> 3<sub>a</sub> 9<sub>a</sub> in May, June, September, October, 1850, and March, 1851; subsequently at 7<sub>m</sub> 2<sub>a</sub>.

NEW YORK.—Continued.

<sup>1</sup> Corrected for daily variation by means of the general table.

<sup>2</sup> Daily means computed by the formula  $\frac{a + 2b + 2c + a'}{6}$  where *a* represents an observation a little before sunrise, *b* one at 3<sub>p</sub>, *c* one at one hour after sunset, and *a'* the morning observation on the following day. The results thus obtained appear, on the average, to be about 0°.5 too high.

<sup>3</sup> New York, Penitentiary Hospital.

<sup>1</sup> Daily means computed by the formula  $\frac{a + 2b + 2c + a'}{6}$  where *a* represents an observation a little before sunrise, *b* one at 3<sup>30</sup>, *c* one at one hour after sunset, and *a'* the morning observation on the following day. The results thus obtained appear, on the average, to be about 0°.5 too high.

<sup>2</sup> Altitude 688 feet, according to Regents' Report.

<sup>4</sup> Series approximately corrected for daily variation; observations often interrupted and hours of observation changed.

<sup>6</sup> Also called *Townsendville* and *Covert*.

<sup>3</sup> Corrected for daily variation by means of the general table.

<sup>6</sup> Observations previous to 1829 not very reliable.

NEW YORK.—Continued.

<sup>1</sup> Daily means computed by the formula  $\frac{a + 2b + 2c + a'}{6}$  where *a* represents an observation a little before sunrise, *b* one at 3<sub>00</sub>, *c* one at one hour after sunset, and *a'* the morning observation on the following day. The results thus obtained appear, on the average, to be about 0°.5 too high.

<sup>2</sup> Also called *Brookhaven*.

1 Daily means computed by the formula  $\frac{a + 2b + 2c + a'}{6}$  where  $a$  represents an observation a little before sunrise,  $b$  one at  $3\frac{1}{2}$ ,  $c$  one at one hour after sunset, and  $a'$  the morning observation on the following day. The results thus obtained appear, on the average, to be about  $0^{\circ}.5$  too high.

7 Observations in part of 1855 and 1856 were made at Arcola and Unionville in Lat. 41°50', Long. 81°00'. Possibly these are different names for the same locality.

8 This series includes observations in 1860-61 at Hammar, about one and a half miles west of Marietta.

9 Observations previous to 1861 were made at Cheviot, about three miles north of Mount Vernon Institute.

10 Altitude 470 feet above low-water in the Ohio River.

OHIO.—Continued.

<sup>1</sup> Observations were made at very irregular hours. They were corrected for daily variation by means of the general table.

<sup>2</sup> Observations in 1839-40-41, and from Dec. 1858, to June, 1859, a period of three years four months, were made at Bellefontaine, about four miles east of Fleming.

<sup>1</sup> The observations from May to October, both inclusive, appear to be about 5° too high. Probably due to a bad exposure of the thermometer during those months.

<sup>2</sup> These observations evidently require a negative correction of about 6°.

<sup>3</sup> The greater part of this series is probably included in the preceding six.

4 This series includes the preceding one.

5 Observations corrected for daily variation.

6 This series was not combined with the preceding one because the record appears defective. It gives the temperature at 9 P. M. lower than at sunrise, which is contrary to experience at other stations.

<sup>1</sup> The observations previous to 1861 were made at Cumberland University at Lebanon, very near Austin.<sup>2</sup> Altitude given as 15 feet above the Gulf.

TENNESSEE.

Table with columns: Spring, Summer, Autumn, Winter, Year, SERIES (Begins, Ends), EXTENT (yrs.mos), OBSERVING (HOURS), OBSERVER, REFERENCES. Contains data for various years and months in Tennessee.

TEXAS.

Table with columns: Spring, Summer, Autumn, Winter, Year, SERIES (Begins, Ends), EXTENT (yrs.mos), OBSERVING (HOURS), OBSERVER, REFERENCES. Contains data for various years and months in Texas.

3 Also called Mine Creek and Sandy Fly.

4 The observations, except for October, November, and December, 1859, were made at Ferris Plantation, about five miles east of Dallas.

<sup>3</sup> Formerly called New Wied.

<sup>4</sup> Also called Phantom Hill.

<sup>6</sup> The observations in July and August, 1867, were made at Long Point, about two miles northeast of Union Hill.

<sup>1</sup> Observations previous to March, 1861, were made at old Camp Floyd.

<sup>2</sup> Observations prior to 1861 at various hours; they have been referred to  $T_m$ ,  $2_s$ ,  $9_a$ ,  $10_p$ , by means of the general table.

<sup>3</sup> Also known as St. George. The series is unreliable; when compared with other stations the results are shown to be much too high; probably due to improper exposure of the instrument, or defective scale.

<sup>1</sup> This series is of very little value on account of great irregularity in the hours of observation.

<sup>2</sup> Observations corrected for daily variation by means of the general table.

<sup>3</sup> The observations, except the first three months of 1861, were made at Tribrook Farm, about three miles northeast of Lexington, by W. H. Ruffner.

<sup>4</sup> Also called Hartwood or Falmouth.

<sup>1</sup> The observations from Feb. 1868, to Dec. 1870, were made by J. A. Brown, near Wytheville, the position being Lat. 36°57', Long. 81°06', Alt. 2400.

<sup>2</sup> The observations from July, 1777, to Aug. 1778, both inclusive, were made at William and Mary College, and are the means of daily extremes between 8 A. M. and 4 P. M., the hours of observation were assumed to be 8<sub>m</sub> 3<sub>p</sub>, and the corresponding correction applied.

<sup>3</sup> Observations corrected for daily variation by means of the general table.

<sup>4</sup> Bihourly, 6<sub>m</sub> to 10<sub>a</sub>, from July, 1857, to Oct. 1858; hourly in Jan. Feb. March, 1859; hourly, 6<sub>m</sub> to 10<sub>a</sub> in April, 1859, and at 7<sub>m</sub> 2<sub>a</sub> 9<sub>a</sub> for remaining 16 months of series. A small correction has been applied to the results for 7<sub>m</sub> 2<sub>a</sub> 9<sub>a</sub>, the rest are assumed to represent very nearly the true mean of the day.

<sup>5</sup> Also known as "Camp Pickett" and "San Juan Island."

<sup>6</sup> The earlier observations were made at Colville Depot, some miles to the southeast, and for five months of 1860 at Harney Depot.

<sup>7</sup> Observations previous to 1855 at ⊙, 9<sub>m</sub> 3<sub>a</sub> 9<sub>a</sub>; they were referred to 7<sub>m</sub> 2<sub>a</sub> 9<sub>a</sub>.

<sup>8</sup> For additional observation in this vicinity, see "Port Townshend."

<sup>9</sup> Observations for four months, in 1841, at 6<sub>m</sub> 2<sub>a</sub> 6<sub>a</sub>, and for four years and one month, from Dec. 1849, to Dec. 1854, at ⊙, 9<sub>m</sub> 3<sub>a</sub> 9<sub>a</sub>; they were referred to 7<sub>m</sub> 2<sub>a</sub> 9<sub>a</sub>.

<sup>10</sup> Observations at 7<sub>m</sub> 2<sub>a</sub> 9<sub>a</sub> after Jan. 1853.

<sup>11</sup> Observations in March and May imperfect.

<sup>12</sup> Also known as "Trout Run Valley" and Wardenville.

WEST VIRGINIA.—Continued.

# GRAPHICAL REPRESENTATION

OF THE PRECEDING

TABULAR RESULTS BY ISOTHERMAL CHARTS.

# EXPLANATION

OF

## THE ISOTHERMAL CHARTS ACCOMPANYING THIS PAPER.

---

THE three accompanying charts have been constructed to show the distribution of the atmospheric temperature within the limits of the United States, on the average during the year, and for the winter and summer seasons.

The great value of the graphical method consists in its capacity of bringing into a connected view the result of a large mass of apparently disconnected figures, and thus presenting their relations to the eye. In the present case, these relations depend on the geographical and hypsometrical features of the country.

The results brought out in these tables form the basis of the charts. They are laid down by means of curves connecting places of equal temperature. These curves may be conceived as forming the intersections of the earth's surface by a series of thermal surfaces of equal temperature one above the other and for equal differences of temperature. The difference, here adopted, is  $4^{\circ}$  Fah., and is the same for all the charts. During the winter season the decrease of temperature between the southern and northern limits of the United States is greater than during the summer season, hence a greater number of curves appear on the chart showing the distribution of temperature in the winter than on that for the year, and the chart for the distribution in summer has the least number of curves. The limiting curves are as follows: For the cold season  $4^{\circ}$  to  $72^{\circ}$  Fah., for the yearly average  $36^{\circ}$  to  $76^{\circ}$  Fah., and for the warm season  $56^{\circ}$  to  $88^{\circ}$  Fah.

From the above designation of the isothermals it follows that each curve must be continuous no matter how tortuous its course may be, that is, it cannot abruptly come to an end; of this instructive examples are presented on the chart for the year by the curve of  $48^{\circ}$  Fah., and on the chart for the summer by the curve of  $68^{\circ}$  Fah. The construction of the curves for the yearly distribution was found slightly more troublesome than those for either of the other charts, owing to the way in which the mean temperature results, from the monthly means, are influenced by the annual variation. Some difficulty was experienced in tracing out the summer curves for the western part of California, owing to the well-known exceptional and remarkable distribution of its temperature, of which more will be said further on.

The want of a reliable hypsometric chart of the United States was seriously felt, not one only on which the existence of hills and mountains should be *correctly* indicated as regards position, but one, on which the actual elevations are indicated by contour lines. A rough hypsometric chart of the latter description was constructed by me to aid in the tracing out of the thermal curves, but the latter are

not what they might be, respecting accuracy in detail, were we in possession of an elaborate hypsometric chart.

On each chart was plotted the mean temperature for the respective period, corrected for daily variation, if necessary, for all the available stations within the area of the chart. On the east of the Mississippi all series extending over five years or more were given to the nearest tenth of a degree of Fahrenheit, those of less than five years' duration were set down to the nearest whole degree.

The decimal point marked the position of the place. For stations west of the Mississippi the limit of 3° was adopted instead of 5°. The curves were constructed with due regard to the elevations of the ground, producing a resemblance, for short distances, of the thermal curves to contour lines of equal elevation. The isothermals thus constructed are *not reduced* to the *sea level* for the following reasons. In the first place, we desire a knowledge of the true distribution of the temperature near the surface to which we are actually exposed and which affects agricultural and other pursuits, and not of any artificial distribution under special, qualified conditions such as the reduction to the sea level; in fact we might as well correct also for propinquity to the sea, for prevailing wind, for proximity of table-land or large lakes, nature of the soil, and a variety of other disturbing causes, which process would finally bring about a close conformity of the isothermals with parallels of latitude, and would represent what has been called the solar climate. Moreover, we do not possess the precise data for such a reduction; thus to experience a diminution of 1° Fah. in the atmospheric temperature, near the surface, the average values vary between 250 and 500 feet of rise, and at elevations beyond a mile, the change in altitude must be greater for the same difference in temperature. Besides, the law is different in the different seasons. It is proper to connect the decrease of temperature in altitude with the decrease of pressure to which it is supposed proportional (when starting from the absolute zero of temperature), a fall of 1° of temperature corresponds approximately to a decrease in pressure of nearly 0.25 inch, the barometric column indicating about 29 inches, and to 0.35 inch nearly for pressure at and below 27 inches.

On the other hand, if the meteorological stations were sufficiently numerous and equally distributed in area, the isothermal curves drawn among them would themselves furnish the best means of ascertaining the separate effects on the climate (temperature) of the various modifying elements of elevation, slope, surface condition (wooded or barren), and many other circumstances.

If we review the indications presented by each chart separately and notice only the leading characteristic features of the distribution of temperature, we may conveniently divide the area of the United States into two parts, viz.: that east of the 100th meridian, of comparatively small elevation, generally below 1000 feet and only exceptionally rising to 4000, and that west of this meridian, with an elevation generally above 4000 feet, and not unfrequently attaining the altitude of 10,000 feet and above.

When referring to the isothermal curves in the description of the charts, those referring to the yearly period will simply be designated as "isothermals," those referring to the winter as "isothermals," and those referring to the summer as "isothermals."

As already pointed out, the position of the isothermal curves is intimately connected with the hypsometric features of the country, and this direct dependence has consequently been made the basis of the above division, greater or less elevation constituting the principal cause of their deflections. This appears, for instance, conspicuously in the isothermal of  $52^{\circ}$ , depending on the direction of the Apalachian range, and in the isothermal of  $44^{\circ}$ , depending on the directions of the Rocky Mountains, the Cascade range, and the Sierra Nevada.

In the *eastern* part of the United States, the distribution of heat appears normal, as indicated by the isothermals between  $44^{\circ}$  and  $68^{\circ}$  which follow, with no great departures, parallels of latitude; in the *western* part, on the contrary, it is altogether more irregular, and the pure solar climate is apparently subverted, the distribution of temperature on the Pacific shore being governed by a system almost at right angles to that in the eastern part, and possessing an *intermediate* system of distribution at the head of the Gulf of California.

In the *winter* months, the proximity of the Gulf stream to the Atlantic sea-board has the effect of *elevating* the temperature in the vicinity of the ocean, the amount being  $0^{\circ}$  in Florida, about  $4^{\circ}$  in North Carolina, and about  $8^{\circ}$  or  $10^{\circ}$  in Massachusetts; in the *summer* months, the effect is reversed, as shown by the isothermals curving southwards; this is due to the cold current running southwards between the coast and the gulf stream, and the depression produced would be still greater but for the circumstance of the prevalence of *westerly* winds which carry the heated air to seaward. The depressing effect, however, in amount, is less than one-half that given for the opposite season. It would appear that in summer nearly the whole of Florida enjoys an almost equal temperature, barely rising above  $80^{\circ}$  Fah.; with this we connect the fact that in Florida summer constitutes the rainy season.

On the yearly average the vicinity of the Atlantic is apparently without any direct effect on the temperature of the coast.

Passing now to the influence of the great lakes we shall find it similar, viz.: a *warming* effect in *winter*, rising to about  $10^{\circ}$ , and a *cooling* effect in *summer*, depressing about  $5^{\circ}$ , whereas, during the year the presence or absence of this body of water would seem to be of no particular consequence as regards mean temperature.

The coldest region is in northern Minnesota and northeastern Dakota, the isocheimal of  $4^{\circ}$  appearing along the low elevations near Red Lake in Minnesota. It is near these regions that the extremely cold waves, which occasionally sweep over the eastern and southern states during the winter appear to enter the United States.

In the western part of the country we recognize as the most remarkable feature, the great uniformity of the distribution of temperature along the Pacific coast as exhibited in the isothermal of  $52^{\circ}$ , skirting the coast for about 650 miles between San Francisco and the northwestern part of Washington Territory; the same feature is indicated by the direction of the isocheimals, approximating to parallelism with that of the coast and again in the isothermal of  $60^{\circ}$ . The direct influence of the Pacific Ocean on the climate of the western states (west of  $100^{\circ}$  longitude) is heightened by the presence of a cool current running southward close along the coast. The presence of the cool ocean, together with the prevailing westerly winds,

sweeping the air which had been resting over the ocean across a great portion of the country, thus impresses the chief character on the climate, viz.: a comparatively high and uniformly distributed *winter* temperature, which is even felt beyond the Rocky Mountains in central Montana, to which latent heat is carried by the moist winds, as clearly exhibited in my Rain Chart<sup>1</sup> for the winter season. With the high winter temperature, we associate the fact of comparatively great precipitation. Secondly, we are impressed with the comparatively low *summer* temperature over the Pacific States; in fact the coldest place in the whole United States, at this season, excepting only the high mountain ranges and peaks, is just outside the Golden Gate, Bay of San Francisco, where we encounter the isothermal of 56°, which appears nowhere else during this season. To exhibit the contrast more forcibly, we have in the corresponding season and latitude on the Atlantic side (near the mouth of Chesapeake Bay, a temperature higher by as much as 18°. With this low summer temperature we connect the fact of but little precipitation.

In *winter* this contrast between the two (opposite) coasts is of the opposite kind, the isocheimal of 52°, off the Golden Gate, corresponding to the isocheimal of 42°, off the mouth of the Chesapeake, a temperature *lower* by 10°. Finally, we notice the extraordinary difference in the range of the mean temperature at the extreme seasons, this being nearly 4° on the Pacific, and nearly 33° on the Atlantic.

We next notice the greater accumulation of heat in valleys than in the plains, the most remarkable instance being that of the Joaquin Valley and its northern prolongation, the Sacramento Valley. This feature is most apparent in the *summer* season, when these valleys seem to become reservoirs of heat, and when their sloping sides are most exposed to insolation. The mean summer temperature in the central part of San Joaquin Valley rises above 84°, when on the sea-coast, close by, it is below 60°. Other instances of this kind are presented on the chart for the summer temperature, by the heated plains of the Columbia River, by the region along the Colorado and Gila Rivers, and, to return to the eastern portion of the country, by the lower valley of the Rio Grande, where the temperature reaches 84°, by the Hudson Valley, and lastly by that of the St. Lawrence.

The hottest region in the United States is along the lower course of the Colorado and Gila Rivers, where we meet with the isothermal of 88°.

It is needless to follow out, in further detail, the various features presented by the charts, since they address themselves sufficiently to the eye, nor has it been deemed necessary to construct isothermal charts for the intermediate seasons of spring and autumn, which, being periods of transition, cannot present features as striking as those exhibited by the extreme seasons.

The total number of results from series plotted on the charts and from which the isothermal curves were constructed are 1300 nearly for the year, 1450 nearly for the winter, and 1500 nearly for the summer. For the base chart, the Smithsonian Institution is indebted to Prof. Francis A. Walker, Superintendent U. S. Census.

### DISCUSSION OF THE DAILY FLUCTUATION OF THE ATMOSPHERIC TEMPERATURE,

WITH

TABLES OF HOURLY VALUES AND OF HOURLY DIFFERENCES FROM THE  
DAILY MEAN, FOR EACH MONTH AND THE YEAR,

AT VARIOUS PLACES IN NORTH AMERICA.

---

*The Daily Fluctuation of the Temperature.*—The daily variation of the temperature, due to the change in the sun's altitude, and dependent upon the length of the day or time of insolation, is principally affected by the amount of aqueous vapor suspended in the atmosphere, by the serenity or cloudiness of the sky, and by the elevation of the ground. As an accumulative effect, the greatest heat will occur some time after the sun has reached its greatest altitude, and the greatest cold some time after its greatest depression. Even in midwinter, in the high latitudes of the Arctic Regions and in the continued absence of the sun, this periodic fluctuation is still perceptible, which may be accounted for by the progress of waves of heat and by its transfer from more southern and still partly insulated regions. In midsummer, when the sun remains above the horizon, the range of the daily fluctuation in the Arctic Regions is very small owing to the small variation in the sun's altitude. As an instance of a small daily fluctuation in a low latitude, Key West near the northern tropic may be cited; here the great humidity of the air tends to confine the daily amplitude within narrow limits. As an example of the opposite effect or of an excessive daily variation, Albuquerque in the valley of the Rio Grande may be cited; it is due to the dryness of the air and the great altitude of the place.

For the investigation of the daily fluctuation hourly observations are quite sufficient, but they should be continued for several years, whenever it is desirable to bring out reliable values of the average daily amplitude for each month. It is in these investigations that the want of self-registering instruments or thermographs is most felt. Our records of temperatures, continued regularly during day and night, even for a single year, are very scanty, and there are but three stations where the observations continue over a sufficiently long period; these are Toronto, Canada, and Mohawk, New York, with full hourly records extending over six years at each place, and Sitka, Alaska, with records over more than twice this period. To Dr.

James Lewis, of Mohawk, is due the merit of having early brought into operation a thermograph of his own invention.

The collection of monthly values for daily fluctuation comprises the results from bihourly, hourly, and semi-hourly observations at 18 stations, see first table accompanying this section of the paper. They are arranged according to latitude. From these the second series of tables is derived as follows: For each month separately, the daily mean temperature  $t$  is subtracted from the observed temperature at any hour, and the difference is set down; a positive sign thus indicates a higher, and a negative sign a lower temperature than that of the day. These tables of differences would furnish the true diurnal fluctuation, if the effect of the annual fluctuation was fully eliminated, and if the daily mean was accurately known. The amount of the annual fluctuation in one day is generally small when compared with the daily fluctuation, and corrections for it need only be applied in extreme cases, as for instance in the Arctic Regions, where the daily range is small in comparison with the annual range; at Van Rensselaer harbor and Port Kennedy the maximum effect for 24 hours amounts to a little more than half a degree (Fah.), on account of which the maximum correction for midnight and the hour preceding it would be one-fourth of a degree, and proportionally less for the intermediate hours. This correction is greatest in April and October, and insensible in July and January.

These tables of hourly differences furnish at once the means of correcting any irregularly observed series, and the mean temperature thus corrected will be the same as that found from an unbroken and regular series of hourly observations. The chief value of these tables lies in this application, and in any special case we have only to select the table for that locality where the thermal conditions may be supposed the same, or at least most nearly resembling those at the locality for which the interpolation or reduction is to be made. For the purpose of facilitating this application, a series of mean values for certain selected combinations of hours is added to each table—these require some further explanation.

These combinations refer to those observing hours from which most probably the nearest approximation to the mean temperature of the day may readily be deduced, not only for the entire year, but also for each month and for any locality, and apply to the cases of record limited to two, three, and four entries a day. The tabular corrections to the selected four hour combination specially, become serviceable for self-registering instruments, when with the least labor (reading off the trace or punctures at those four hours) we wish to obtain a reliable daily mean short of the tedious process of operating on 24 equidistant records.

About the year 1815, Prof. C. Devey examined<sup>1</sup> the hours 7 A. M., 2 and 9 P. M., adopted by the Manheim<sup>2</sup> Meteorological Society, with reference to their applicability to our climate, and in 1816 and 1817 instituted a short series of hourly observations at Williamstown which proved the fitness of these hours for observation in the United States. These results he communicated to Secretary Calhoun,

<sup>1</sup> Annual Report of the Board of Regents of the Smithsonian Institution for the year 1857, p. 310; also annual report for 1860, p. 413.

<sup>2</sup> In Baden, Germany.

and the hours 7, 2, 9 were, in consequence, adopted for the system of meteorological observations at the military posts of the United States, organized in 1819 under the direction of the surgeon-general of the United States Army. Although these hours were at one time abandoned (between 1841 and 1854, when the epochs a little before sunrise, 3 and 9 P. M. were substituted), they were re-established in 1855, mainly through the exertions of Dr. Coolidge, U. S. A. The convenience and satisfactory character of the results of these hours, also led to their adoption in the meteorological observations undertaken conjointly by the United States Patent Office and the Smithsonian Institution in 1854, and they have since been adhered to by the latter Institution. The recognition of the fact that the results by the three hours 7, 2, 9 can be greatly improved by taking one-fourth of the ordinates at 7, 2, and twice 9 in the place of one-third of the ordinates at 7, 2, 9, appears also to be due to Dr. Dewey.

From the present collection of results it appears that the homonymous hours, 10, 10, give differences of less than  $\pm 0^{\circ}.5$  in the annual mean, that the triplets, 6, 2, 9, and equidistant hours, 6, 2, 10, are of nearly equal value, and but slightly superior to the preceding pair of hours, the former combination producing a higher, the latter a lower mean than the true value of twenty-four equidistant observations, but deviating less than  $0^{\circ}.4$ . The combination 7, 2, 9, produces a result nearly  $0^{\circ}.5$  in excess, whereas the modification 7, 2, 9 (*bis*) diminishes this difference to nearly  $0^{\circ}.1$  with a change of signs for different stations. The four-hour combination 3, 9, 3, 9, adopted by the Royal Society, is the best of all, being generally less than  $0^{\circ}.1$  above the true daily mean. In the following table of differences from the daily mean, of the average temperature observed at 7, 2, 9, the sign + indicates an excess, the sign — a defect of the latter average. The *first* line for each station answers to the combination  $\frac{1}{3}$  (7, 2, 9), the *second* to the modification  $\frac{1}{4}$  [7, 2, 9 (*bis*)].

With the exception of Key West, where the proximity of the gulf stream produces an anomaly, the combination  $\frac{1}{3}$  (7, 2, 9 (*bis*)) is superior to the simple mean for the three hours, and, in general, the results at the different stations are sufficiently accordant to permit monthly average values of differences to be taken; omitting, therefore, the first three stations and the last station, we find the following mean values applicable to most localities in the United States between latitudes  $30^{\circ}$  and  $45^{\circ}$  and east of the Mississippi.

Table of average differences, in temperature, of the mean derived from the observations at 7, 2, 9, also as deduced from 7, 2, 9 (*bis*), from the true daily mean; + in excess, - in defect of the true value. Expressed in degrees of the Fahrenheit scale.

In order to make use of the values of this table, as *corrections* to means derived from observations at these hours, the *sign is to be reversed*.

The above tabular values are derived from more than 22 years of hourly observations made at eight stations. The assumption that the average of *hourly* observations equals the daily average, is so nearly correct as to require no further consideration; thus at Thunder Bay Island, Mich., the mean of 24 observations taken at the full hours is 42°.84, the mean of 24 observations taken at the intermediate half hours is 42°.83, which is also the mean of the 48 semi-hourly observations.

*Times of Sunrise and Sunset in different Latitudes and for every tenth day in each month.*—We meet frequently, particularly in the older meteorological observations, with records taken at the times of sunrise and sunset; this practice, now generally superseded by better selected fixed epochs, still obliges us to resort to tables of times of sunrise and sunset, with the day of the month and the latitude as arguments, whenever we aim at a careful reduction of the recorded temperatures.

In computing such a table for various latitudes and to answer for any year, the deduced times can only be more or less close approximations on account of the small variations, in different years, in the sun's declination, in its distance, and in the equation of time, on the same nominal day. Fortunately a few minutes of error with a tendency to cancel itself for long series, are of little moment in the meteorological record. The tabular quantities will generally be found correct within 2 or 3 minutes, excepting in the higher latitudes, where this limit may occasionally be slightly exceeded.

The times were computed by the formulæ

$$\cos t = \frac{\cos \zeta - \sin \phi \sin \delta}{\cos \phi \cos \delta} \quad \text{and} \quad \zeta = 90^\circ + r - \pi + s + d = 90^\circ 51' \text{ nearly.}$$

|                                  |                                    |
|----------------------------------|------------------------------------|
| where $\phi$ = latitude,         | $r$ = refraction in horizon,       |
| $\delta$ = sun's declination,    | $s$ = sun's semidiameter,          |
| $\zeta$ = sun's zenith distance, | $\pi$ = sun's horizontal parallax, |
| $t$ = hour angle,                | $d$ = dip of horizon.              |

The apparent time was changed to mean time by application of the equation of time ( $E$ ).

The value of  $\delta$  may vary in different years, for the same nominal day, by  $\pm 9'$  nearly, from its average amount; the value of  $s$  hardly varies as much as  $\pm 0'.5$ ; the variations in  $E$  for the same nominal day amount to less than  $\pm \frac{1}{4}$  of a minute, and the maximum half-daily change is of the same amount. The use of the value of  $\delta$  for the meridian of Washington instead of any other meridian within the limits of the United States, cannot occasion an error as great as that previously noted for  $\delta$ . The changes in the horizontal refraction due to extremes of temperature (and atmospheric pressure) may amount, at most, to about  $\pm 8'$  from the mean state, assumed at 35' (temp. 50° Fah.; pressure 30 inch.). The value of  $\zeta$  was taken as constant,  $\delta$  was taken from the ephemeris for the times of sunrise and set for those parts of the year where the use of the meridional value would introduce a notable defect. Both,  $\delta$  and  $E$ , refer to average years.

Time of Sunrise.

Latitude.

<sup>1</sup> Smithsonian Contributions to Knowledge, No. 146; Washington, 1862.

<sup>2</sup> The temperatures for the 5 hours, 11 to 3, were obtained by a graphical process, and the above means were taken from 24 values. The reckoning being in old style and easterly, our months begin and end 11 days earlier than those to which the above numbers correspond. The original record is given in Reaumur's scale, it is here converted in Fahrenheit's scale. Interpolated values for 4 and 5 A. M., January, 1861, —0°.63 and —0°.53 (Reaumur).

TABLES OF MEAN TEMPERATURES.

| Hour.                                                                                                                                                                                                                                                                                                                        | Jan.   | Feb.    | Mar.   | Apr.   | May.   | June.  | July.  | Aug.   | Sept.  | Oct.   | Nov.   | Dec.   | Year.  |

N. B. The observer remarks that the indications of the instrument are absolutely correct, but that its exposure was not unexceptionable; the locality, though in the shade and on the north side of the house, being accessible to the influence of the sun between 2½ or 3 P. M., and sunset or to within half an hour previous to sunset. In 1865 the station was movable to avoid this influence, in 1866-7 it was tolerably free from disturbance, in the winter 1868-9 a screen was erected to the westward. I have omitted the results in all months marked \*, considering the indications affected from the above cause. [S.]

| Mean             | 28.82  | 35.40  | 37.07  | 42.96  | 54.53  | 62.33  | 71.53  | 66.36  | 56.07  | 45.03  | 35.94  | 31.35  | 47.37  |
| No. of days      | 13     | 10     | 14     | 15     | 14     | 11     | 10     | 11     | 11     | 15     | 30     | 23     |        |

It is apparent that the small number of observations is the principal cause of certain anomalies presented in the above means.

<sup>1</sup> The observations between June, 1840, and Dec. 1841, inclusive, were taken bi-hourly, and those between June, 1840, and Feb. 1841, inclusive, 25 minutes after the full hours; those between March, 1841, and Dec. 1841, inclusive, 15 minutes after the full hours. By interpolation the results were changed to refer to the full hours and for every hour. The means for each hour for the whole period of observations were then combined separately for each month. There is no record for Jan., Feb., and March, 1843. For record see "Observations at the magnetical and meteorological Observatory." Washington, D. C., 1847, four volumes.

<sup>2</sup> MS. in Sm. Coll.  
 The record begins with Jan. 1851, but is not sufficiently regular for use till May, 1851. Numbers interpolated at the following hours: 3 A. M. May, 1851; 9 A. M., 3 P. M., and 9 P. M. May, June, July, 1851. The annual means for 10, 11 P. M., 0, 1, and 2 A. M. are graphically interpolated.  
 There are many omissions in the record. Some scattering observations between the hours 10 P. M. and 3 A. M. cannot be utilized.

The following values for certain combinations of hours were obtained by a process of graphical interpolation, the above monthly results having been plotted on a suitable scale for that purpose:—

|                        |      |      |      |      |      |      |      |      |      |      |      |      |      |
|------------------------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| Comb's                 | +0.3 | +0.5 | -0.2 | +0.1 | +0.9 | +1.4 | +0.5 | +0.3 | -0.1 | +0.4 | +0.2 | +0.3 | +0.4 |
| 7, 2, 9                | +0.2 | -0.1 | -0.7 | -0.4 | -0.1 | +0.2 | -0.4 | -0.3 | -0.7 | -0.4 | -0.2 | 0.0  | -0.2 |
| 7, 2, 9 <sup>hrs</sup> | -0.5 | -0.1 | +0.2 | +0.4 | +0.2 | -0.2 | +0.1 | +0.4 | +0.5 | +0.2 | +0.4 | 0.0  | +0.1 |

The above results are of comparatively little value on account of the small number of observations.

| <p><sup>1</sup> From Prof. Guyot's Meteorological and Physical Tables, Smithsonian Misc. Coll.; Washington, 1858.<br/>Table by Dove.</p> |                                                                                                              |       |       |       |       |       |       |       |       |       |       |       |       |

For systematic comparison of the law of the diurnal fluctuation we present the resulting hourly numbers, on the yearly average as contained in the table of differences, in an analytical form, making use of Bessel's periodic function—<sup>1</sup>

$$t = A + B_1 \sin(\theta + C_1) + B_2 \sin(2\theta + C_2) + B_3 \sin(3\theta + C_3) + \text{etc.}$$

<sup>1</sup> See Bessel's paper in the *Astronomische Nachrichten*, No. 136 (May, 1828). His first publication on the subject is contained in the *Literary Gazette of Jena*, in 1814.

See also a memoir by M. A. Bravais in "Voyages en Scandinavie, en Laponie, au Spitzberg et aux Feroe, pendant les années 1838, 1839, et 1840, Météorologie." An extract is given by M. J. Haeghens in the "Annuaire Météorologique de la France pour 1850, p. 93.

See also Sir J. Herschel's Article, "Meteorology" in the *Encyclopædia Britannica*. Reprint, p. 144.

The general formulæ given in this article, when applied to the case of 24 equidistant observations in a cycle, change into the following expressions, which were employed for the numerical computations:

$$A = \frac{1}{24} (y_1 + y_2 + y_3 + \dots + y_{24})$$

$$12 a_1 = 0.966 (y_1 - y_{11} - y_{13} + y_{23}) + 0.866 (y_2 - y_{10} - y_{14} + y_{22}) + 0.707 (y_3 - y_9 - y_{15} + y_{21}) \\ + 0.500 (y_4 - y_8 - y_{16} + y_{20}) + 0.259 (y_5 - y_7 - y_{17} + y_{19}) - y_{12} + y_{24}$$

$$12 b_1 = 0.259 (y_1 + y_{11} - y_{13} - y_{23}) + 0.500 (y_2 + y_{10} - y_{14} - y_{22}) + 0.707 (y_3 + y_9 - y_{15} - y_{21}) \\ + 0.866 (y_4 + y_8 - y_{16} - y_{20}) + 0.966 (y_5 + y_7 - y_{17} - y_{19}) + y_6 - y_{18}$$

$$B_1 = \sqrt{a_1^2 + b_1^2} \quad \text{and} \quad \tan C_1 = \frac{a_1}{b_1}$$

$$12 a_2 = 0.866 (y_1 - y_5 - y_7 + y_{11} + y_{13} - y_{17} - y_{19} + y_{23}) + 0.500 (y_2 - y_4 - y_8 + y_{10} + y_{14} - y_{16} - y_{20} + y_{22}) \\ - y_6 + y_{12} - y_{18} + y_{24}$$

$$12 b_2 = 0.500 (y_1 + y_5 - y_7 - y_{11} + y_{13} + y_{17} - y_{19} - y_{23}) + 0.866 (y_2 + y_4 - y_8 - y_{10} + y_{14} + y_{16} - y_{20} - y_{22}) \\ + y_3 - y_9 + y_{15} - y_{21}$$

$$12 a_3 = 0.707 (y_1 - y_3 - y_5 + y_7 + y_9 - y_{11} - y_{13} + y_{15} + y_{17} - y_{19} - y_{21} + y_{23}) \\ - y_4 + y_8 - y_{12} + y_{16} - y_{20} + y_{24}$$

$$12 b_3 = 0.707 (y_1 + y_3 - y_5 - y_7 + y_9 + y_{11} - y_{13} - y_{15} + y_{17} + y_{19} - y_{21} - y_{23}) \\ + y_2 - y_6 + y_{10} - y_{14} + y_{18} - y_{22}$$

$$12 a_4 = 0.500 (y_1 - y_2 - y_4 + y_5 + y_7 - y_8 - y_{10} + y_{11} + y_{13} - y_{14} - y_{16} + y_{17} + y_{19} - y_{20} - y_{22} + y_{23}) \\ - y_3 + y_6 - y_9 + y_{12} - y_{15} + y_{18} - y_{21} + y_{24}$$

$$12 b_4 = 0.866 (y_1 + y_2 - y_4 - y_5 + y_7 + y_8 - y_{10} - y_{11} + y_{13} + y_{14} - y_{16} - y_{17} + y_{19} + y_{20} - y_{22} - y_{23}) \\ \text{etc.}$$

The values  $B_2 B_3 B_4 \dots$  and  $C_2 C_3 C_4 \dots$  are found in a similar manner as  $B_1$  and  $C_1$ .

For 12 equidistant observations in a cycle, as in our bi-hourly series, we use the formulæ:

$$A = \frac{1}{12} (y_1 + y_2 + y_3 + \dots + y_{12})$$

$$6 a_1 = 0.866 (y_1 - y_5 - y_7 + y_{11}) + 0.500 (y_2 - y_4 - y_8 + y_{10}) - y_6 + y_{12}$$

$$6 b_1 = 0.500 (y_1 + y_5 - y_7 - y_{11}) + 0.866 (y_2 + y_4 - y_8 - y_{10}) + y_3 - y_9$$

$$6 a_2 = 0.500 (y_1 - y_2 - y_4 + y_5 + y_7 - y_8 - y_{10} + y_{11}) - y_3 + y_6 - y_9 + y_{12}$$

$$6 b_2 = 0.866 (y_1 + y_2 - y_4 - y_5 + y_7 + y_8 - y_{10} - y_{11})$$

$$6 a_3 = -y_2 + y_4 - y_6 + y_8 - y_{10} + y_{12}$$

$$6 b_3 = y_1 - y_3 + y_5 - y_7 + y_9 - y_{11}$$

$$6 a_4 = 0.500 (-y_1 - y_2 - y_4 - y_5 - y_7 - y_8 - y_{10} - y_{11}) + y_3 + y_6 + y_9 + y_{12}$$

$$6 b_4 = 0.866 (y_1 - y_2 + y_4 - y_5 + y_7 - y_8 + y_{10} - y_{11})$$

etc.

The values  $B_1 B_2 B_3 B_4 \dots$  and  $C_1 C_2 C_3 C_4 \dots$  are found as stated.

The above expressions, together with others, are given in Coast Survey Report of 1862, Appendix, No. 22 (with erratum in 1866 report).

We retain three periodic terms as generally sufficient for our purpose. The angle  $\theta$  counts from midnight at the rate of  $15^\circ$  an hour; at those stations where the observations were not made at the full hours, the angles  $C_1, C_2, C_3$  were changed in the expression for  $t$  in order to refer them to the same epoch. The table also contains the latitude ( $\phi$ ), the longitude ( $\lambda$ ), the elevation ( $h$ ) of the station, and the number of years ( $n$ ) of observation. The column headed  $T$  contains the annual mean temperature or the mean of the twelve monthly averages.

*Numerical quantities in Bessel's function for the DAILY fluctuation of temperature, on the yearly average.*

A better insight into the systematic character of the co-efficients and epochal angles, as far as they depend upon the latitude and local conditions, can be had by a combination of the results into groups. The hourly values for the stations forming a group were combined into mean values, and then submitted to the numerical process, which produced the following results:—

*Types of the daily fluctuation of the temperature on the yearly average.*

- Group I. The four Arctic stations.  $\phi_m = 74^\circ.7$   $\lambda_m = 82^\circ.5$ . 4 years.  
 $t = + 2^\circ.23 + 2^\circ.11 \sin(\theta + 243^\circ.6) + 0^\circ.14 \sin(2\theta + 66^\circ.3)$   
 $+ 0.04 \sin(3\theta + 216^\circ).$
- Group II. The Alaska station.  $\phi = 57^\circ.1$   $\lambda = 135^\circ.3$ . 13 years.  
 $t = + 43^\circ.03 + 3^\circ.46 \sin(\theta + 240^\circ.0) + 0^\circ.66 \sin(2\theta + 66^\circ.6)$   
 $+ 0.09 \sin(3\theta + 330^\circ).$
- Group III. Four stations in Canada and  
 Northern New York.  $\phi_m = 44^\circ.3$   $\lambda_m = 77^\circ.8$ . 16 years.  
 $t = + 44^\circ.14 + 5^\circ.08 \sin(\theta + 225^\circ.5) + 0^\circ.89 \sin(2\theta + 48^\circ.2)$   
 $+ 0.21 \sin(3\theta + 50^\circ).$

Group IV. Four stations in Mass.,

Conn., and N. Y.  $\phi_m = 41^\circ.7$   $\lambda_m = 72^\circ.6$ . More than 4 years.  
 $t = +48^\circ.65 + 6^\circ.27 \sin(\theta + 232^\circ.7) + 1^\circ.38 \sin(2\theta + 61^\circ.1)$   
 $+ 0.10 \sin(3\theta + 359^\circ)$ .

Group V. Three stations in Penn.,

and Dist. of Col.  $\phi_m = 39^\circ.6$   $\lambda_m = 75^\circ.8$ . 15 years.  
 $t = +53^\circ.38 + 6^\circ.55 \sin(\theta + 225^\circ.7) + 1^\circ.27 \sin(2\theta + 48^\circ.1)$   
 $+ 0.35 \sin(3\theta + 36^\circ)$ .

Group VI. Two Gulf stations.

$\phi_m = 27^\circ.4$   $\lambda_m = 84^\circ.9$ . 2 years.  
 $t = +73^\circ.44 + 2^\circ.75 \sin(\theta + 227^\circ.8) + 0^\circ.70 \sin(2\theta + 57^\circ.5)$   
 $+ 0.17 \sin(3\theta + 31^\circ)$ .

The hourly means from which these expressions were derived are contained in the following table:—

*Observed Daily fluctuation of temperature, on the yearly average, for groups of stations.*

| Hour.  | I.                                                                    |        |                                                         |                                                   |                                                    |                           | II.                                                                   |        |                                                         |                                                   |                                                    |                           |

| 11     | +1.6                                                                  | +2.9   | +2.8                                                    | +4.7                                              | +4.1                                               | +1.8                      | -1.5                                                                  | -2.1   | -2.2                                                    | -3.2                                              | -3.3                                               | -1.2                      |

At several stations, interpolation, graphical or analytical, was required to complete the hourly values before they could be combined into groups. Frankford Arsenal and Philadelphia values were united into a mean and then combined with the Washington values.

By means of the equations we readily find the following times of greatest, least, and average heat of the day and of the daily range, on the yearly average.

| Group           | Max. at                        | Min. at                        | Mean at                       |                                | Range. |
|-----------------|--------------------------------|--------------------------------|-------------------------------|--------------------------------|--------|
|                 | P. M.                          | A. M.                          | A. M.                         | P. M.                          |        |

| III . . . .     | 2 38                           | 4 31                           | 9 12                          | 8 11                           | 10.6   |
| IV . . . .      | 1 46                           | 4 24                           | 8 53                          | 7 42                           | 13.1   |
| V . . . .       | 2 28                           | 4 28                           | 9 01                          | 7 54                           | 13.6   |
| VI . . . .      | 2 12                           | 4 54                           | 9 04                          | 7 49                           | 5.9    |
| Mean III, IV, V | 2 17                           | 4 28                           | 9 02                          | 7 56                           | 12.4   |

The results of the daily fluctuation, as given above, may be summed up as follows:—

The daily range diminishes from about latitude 40° in either direction north or south. The precise latitude of maximum range cannot yet be given. Diagram A shows the extremely small ranges in latitude 75° and in latitude 27°, the former produced by the small range in the sun's altitude during the Arctic day, the latter by the equalizing effect of the aqueous vapor near the Gulf coast notwithstanding the sun's great daily range in altitude near the tropic of cancer. Diagram B shows the large daily range for the stations comprising groups IV and V, and the somewhat smaller one for group III.

The greatest heat of the day is reached earlier in the high than in the low latitudes; with the mean annual temperature near or below the freezing point, the warmest time of the day is about 1½ P. M., in the middle and lower latitudes this epoch changes to 2¼ P. M. The greatest depression in the daily fluctuation occurs in the Arctic regions about two hours after midnight, in the temperate zone about

4½ A. M. or about one hour and a half *before* sunrise. The epochs of mean daily temperature are subject to less variations with respect to latitude than the epochs of the daily extremes. In the Arctic regions the mean temperature of the day is reached about 8 A. M., in the temperate regions about 9 A. M., and again about 7½ P. M. and about 8 P. M. respectively.

The material for the discussion of the daily fluctuation for stations in the Mississippi valley and in the western states and territories is yet wanting.

The annual variation in the range of the daily fluctuation is shown in the following table. From want of completeness in the records the tabular numbers, in many instances, are the result of interpolation, and they can only be considered as close approximations.

Monthly means of the RANGE of the daily fluctuation.

<sup>1</sup> Omitting Brooklyn as too irregular.

DIAGRAM C.

DIAGRAM D.

At all stations, of the above table, between the Gulf of Mexico and the Arctic Sea, the daily range is a minimum in December; this, however, is the only feature

they have in common, as shown in diagrams C and D. In the first diagram the curves for the northern stations appear single-crested, in the second the curve of the middle latitude stations is double-crested and that of the Gulf stations exhibits three or more elevations and depressions, all ill-defined. The marked feature of the low latitude range is its great uniformity throughout the year. In the Arctic regions, with the returning day, the range suddenly rises to its maximum in March; in Canada and northern New York the range is greatest in July or about the time of greatest heat; along the coast from Massachusetts to the District of Columbia the range attains two maxima, one early in June the other late in September, with an intermediate depression of range during the hottest season. As our observations become more extended, other features in the march of the daily temperature will undoubtedly make their appearance, and those already recognized will become better defined. At San Francisco especially, it would be interesting to have a series of hourly observations, extending at least over one year, this locality being otherwise noted for anomalous temperature relations. According to Dr. Gibbons the coldest and warmest periods of the day are not far from sunrise and noon, and by taking the differences of the mean monthly temperatures at these times, as given in the Smithsonian report for 1854, p. 231 and foll. For the years 1851 to 1854, I obtain the following table of daily range of temperature at San Francisco.

|                    |       |                     |       |
|--------------------|-------|---------------------|-------|
| January . . . . .  | 12°.1 | July . . . . .      | 15°.7 |
| February . . . . . | 14.0  | August . . . . .    | 12.8  |
| March . . . . .    | 15.3  | September . . . . . | 14.9  |
| April . . . . .    | 16.5  | October . . . . .   | 16.1  |
| May . . . . .      | 14.9  | November . . . . .  | 13.7  |
| June . . . . .     | 16.2  | December . . . . .  | 11.5  |

These numbers are approximations only, yet they indicate a comparatively large range, a minimum range in December and two maxima—one in spring, the other in autumn.

The modification which the daily fluctuation undergoes in the course of a year can be advantageously brought out by a comparison of its value in December when near the least, with its value in June when not far from its greatest development.

The fluctuations observed at Van Rensselaer, Port Foulke, Port Kennedy, and Boothia Felix were united into a mean, those at Thunder Bay Island, Toronto, Mohawk, Amherst, and Philadelphia into another, and those at Fort Morgan, Key West, and Galveston into a third; these localities are designated, Arctic stations, Temperate stations, and Gulf stations respectively.

Before taking means, the record for Galveston, Texas, was made complete by interpolation.

TABLES OF DIFFERENCES OF MEAN TEMPERATURES. 159

| 7     | +0.2                 | +0.2  | +0.5                    | +2.8  | +0.4               | —0.4  |
| 8     | +0.2                 | —0.5  | +0.1                    | +0.2  | 0.0                | —1.1  |
| 9     | +0.1                 | —1.3  | —0.4                    | —1.7  | —0.3               | —1.4  |
| 10    | +0.1                 | —2.0  | —0.8                    | —2.9  | —0.6               | —1.8  |
| 11    | —0.1                 | —2.6  | —1.2                    | —4.0  | —1.1               | —1.9  |

The above numbers are plotted on diagrams E, F, and G. These diagrams show plainly, in December the morning minimum later and the afternoon maximum earlier than in June; also the morning and afternoon epochs of mean daily temperature later in December (nearly two hours) than in June, but in the temperate latitudes the afternoon hour (8 o'clock) answers for the time of the winter as well as for the time of the summer solstice.

DIAGRAM E.

DIAGRAM F.

DIAGRAM G.

The vicinity of San Francisco, Cal., probably presents the greatest anomaly yet noticed. Dr. H. Gibbons remarks<sup>1</sup> that at San Francisco the warmest period of the day in winter is from 1 to 2 P. M., but in summer (May to August) it is an hour or two earlier owing to the sea breeze, which springs up about noon or soon after, instantly depressing the temperature. In the season of the westerly breezes the temperature is rapidly reduced and the change is effected long before sunset, after which time the thermometer shows but little variation till the following morning. Under the influence of this brisk sea breeze, the rays of a high sun fail to impart any appreciable heat to the air. These conditions are quite local and the attending phenomena respecting the daily and annual fluctuations are confined to the vicinity of the Bay of San Francisco, though traces of it appear at all stations along the western coast exposed to the immediate influence of the westerly winds from the Pacific ocean. Observations of the daily march of the temperature in these localities are specially desirable. For the study of the effect of height on the daily fluctuation no material is at present available, but our records show that under this condition it may become quite excessive; at elevated regions the air is comparatively dry and the sun's rays reach the ground but little impeded, while at night radiation is going on with great energy from the comparative absence of an absorbing medium. The great interior basin bounded on the east by the Rocky Mountains and the

<sup>1</sup> The climate of San Francisco; Smithsonian Annual Report for 1854, p. 231 and foll.

Sierra Madre, on the west by the Sierra Nevada and including the regions of the Colorado River, also the northern portion of the Rio Grande, furnishes many interesting examples of an excessively large daily range, the magnitude of which may, in a measure, be inferred from the following comparisons of the difference of temperature at the observing hours 7 A. M. and 2 P. M., or at the time of sunrise and 3 P. M., for a few selected places, located in New Mexico, Texas, Arizona, and California. With the exception of Fort Yuma, which is but 200 feet above the sea level, these stations are all at considerable elevations.

Average difference in the temperature, between sunrise and 3 P. M., or between 7 A. M. and 2 P. M., taken from the monthly means at these hours of observation. [Army Met. Regs. for 1855 and 1860.]

| Year . . . . .                           | 30                   | 28                    | 26                    | 24                      | 23                      | 23                   | 22                 | 22                      | 21                  | 24               |

The mean daily range, for any month or for the year, at any of the above stations is necessarily several degrees higher than the corresponding tabular difference since the morning and afternoon extremes do not take place at the hours of observation; even the tabular numbers, when contrasted with the observed daily range in other parts of the United States, appear excessive, and imperfect as they must be owing to the short number of years and the great variability of the quantities themselves, the annual fluctuation of the differences given in the last column presents quite a regular double crested curve. The maximum daily range occurs in March and April, a second smaller maximum in October with minima in July and August, and again in December, the latter minimum being apparently a common feature within the boundaries of the United States. The great development of the daily fluctuation at Albuquerque, N. M., would recommend this station as a suitable locality for an extended hourly series (to be recorded with a self-registering instrument). Such observations would greatly assist in establishing corrections to

the mean temperature derived from the ordinary hours of observation (7 A. M. and 2 and 9 P. M.) in order to refer them to the true daily mean.

A table of the daily fluctuation for this place would answer for most stations situated within the elevated and arid region generally known as the great interior basin, as well as for the regions of the upper Rio Grande and of western Texas.

In some instances the recorded mean monthly difference between the morning and afternoon temperatures rises to 40°, and if the observations are to be trusted to 45°; the corresponding daily incidental range is equally great and for the regions described above it is not uncommon to meet, in the morning, with a temperature below the freezing point and to experience in the afternoon of the same day a heat rising to 70 or 80° Fah.

*Variability of the temperature at any hour of the day from the normal value of that hour.*

To complete the investigation of the general laws of the daily fluctuation we have yet to inquire into the amount of digression of the monthly mean of any observed hourly temperature when compared with its normal value.

These irregular variations are most readily ascertained by a comparison of the *monthly means* for each hour of the day, given separately for a *series* of years, with the mean of the combined years for each hour. By this method we completely free our results from the effects of the annual fluctuation, and have the advantage of presenting the probable error to the hourly temperatures, as given in the first set of tables for each month, provided the particular table was derived from a *single year* of observations; if the tables are constructed from *n* years, the probable errors require a division by  $\sqrt{n}$  in order to represent the probable uncertainties of their tabular numbers.

With a special view to this investigation the Mohawk table of hourly temperatures is given in full, from 1860 to 1868, only six years of hourly observations, however, could be utilized for the present purpose. At Philadelphia, the Girard College series furnished hourly means for nearly 5 years from 1840 to 1845. At Sitka a series of hourly observations (with omissions of 5 readings in each day) was taken from the records of the observatory, for 5 years, selecting 1847-8-9 and 1862-3-4. For Toronto, Can., the results are copied from Table VII<sup>1</sup> of the

<sup>1</sup> The following is, in part, a copy of the Toronto table.

| Hour.     | Jan. | Feb. | March. | April. | May. | June. | July. | August. | Sept. | Oct. | Nov. | Dec. | Oct. to March inclusive. | Apr. to Sept. inclusive. |

“Results of meteorological observations made at the magnetical observatory, during the years 1860-1-2.” G. T. Kingston, Director. This table is headed “Probable variability of the monthly means of temperature at each of the 6 observation hours, in a single year, together with their half-yearly and yearly averages, from the years 1854 to 1862 inclusive,” and the deduction from the results is stated as follows: The *warm* hours are most liable to disturbances of temperature in the *warm* months, and the *cold* hours in the *cold* months, and altogether the abnormal digressions are greater in the colder half year than in the warmer.

A series of hourly observations continued for 6 years is barely sufficient for the investigation and the results for the three winter months (Dec., Jan., Feb.) were contracted into a mean, also the results of the three summer months (June, July, Aug.); it was not deemed necessary to investigate the six remaining months, since the law is seen to change gradually from season to season, the variability of the temperature of any hour being nearly the same about or after the epochs of the equinoxes.

Probable error of the monthly mean temperature for any hour of the day, derived from a series of years.

| Hours of day. | Winter.  |         |        |        |      | Summer.  |         |        |        |      |

The Toronto results are in the main confirmed by those at the other stations, and there is no doubt a much closer accordance would be obtained from longer series of records. In winter the maximum variability occurs a few hours after midnight, or about the period of the maximum cold of the day; in summer the reverse of this happens, the maximum variability then occurs about 3 P. M., or about the period of maximum heat. In winter the greatest constancy is noted about 2 P. M., but in summer the temperature is most steady some hours after midnight.

The progression of the tabular numbers from hour to hour is quite regular, particularly for Mohawk. The amount of variation is nearly the same at Toronto and Mohawk, but less at Philadelphia and Sitka. In general the variability in winter is more than double that of summer; this latter variation will be found further investigated under the head of the annual fluctuation.

In winter the maximum variability at any hour is to the minimum variability as 5 to 4, and in summer as 8 to 5.

Multiplying the above average probable errors  $\pm 2^{\circ}.8$  in winter, and  $\pm 1^{\circ}.2$  in summer by  $\sqrt{30.4}$  or by 5.5 nearly, we have an approximation to the probable error of an observed temperature at any hour of the day at these seasons, with reference to the normal values of that hour, month, and season. These quantities are  $\pm 15^{\circ}$  and  $\pm 7^{\circ}$  respectively.

Any attempt to deduce, for any given time and place at the earth's surface, even approximately, the daily fluctuation of the temperature, as far as it depends upon the variations of the sun's altitude<sup>1</sup> and with consideration of the loss of heat by absorption while passing through various depths of atmosphere,<sup>2</sup> must lead to

<sup>1</sup> Let  $\zeta$  = the sun's zenith distance,  $\delta$  its declination,  $t$  the hour angle, then for the latitude  $\phi$   
 $\cos \zeta = \sin \phi \sin \delta + \cos \phi \cos \delta \cos t$ ,

from which expression the altitude or depression of the sun for any hour of the day may be computed.

<sup>2</sup> If we treat the *length* of the oblique path of a ray of heat passing through the atmosphere simply as a geometrical problem, it is given by

$$l = \sqrt{r^2 \cos^2 \zeta + 2rh + h^2} - r \cos \zeta,$$

hence for the case of a horizontal ray (irrespective of refraction),

$$L = \sqrt{2rh + h^2},$$

where  $r$  = the earth's radius and  $h$  = the height of the atmosphere. Taking for instance  $h = 45$  st. miles, at which elevation twilight yet indicates the presence of air capable of reflection, and  $r = 3956$  miles, we find that horizontal ray must traverse nearly 600 miles of atmosphere or 13.3 times the vertical thickness, if  $h = 74$  miles, which is the average height at which shooting stars become incandescent when coming in contact with the atmosphere, the length of path is about 770 miles or 10.4 times the vertical thickness. The decrease of heat of inclined rays is greater than that resulting from the inverse proportion of the length of tract, and is due to the density of the air increasing geometrically, while the depth increases arithmetically. The following measures of atmospheric tract and of calorific effect on a surface vertically exposed to the ray, is extracted from a table given in the Encyclopædia Britannica (8th edition), article, climate; it supposes that of one thousand rays, vertically incident on the outer boundary of the atmosphere, only 750 will be transmitted through it and received on the ground. The numbers in the column headed "*H*" are computed by the formula  $(\frac{2}{3})^{\sec \zeta}$ , given in the article meteorology, according to which only 667 rays reach the ground. The last two columns contain the number of rays incident on a horizontal surface, obtained by multiplying the numbers in the preceding columns by  $\cos \zeta$ .

| Zenith distance.<br>$\zeta$ | Length of atmospheric tract. | Rays transmitted.<br>( <i>L</i> ) | $(\frac{2}{3})^{\sec \zeta}$<br>( <i>H</i> ) | <i>L</i> cos $\zeta$ | <i>H</i> cos $\zeta$ |

| 90                          | 37.850                       | 0                                 | 0                                            | 0                    | 0                    |

unsatisfactory results, for the reason that the distribution of heat passing into the atmosphere directly and indirectly through surface radiation, evection, and conduction, and the amount parted with by radiation during the night, as well as the modifying influence of the aqueous vapor, present far too complex phenomena to be accounted for numerically. We have already seen that the absolute amount of vapor and the relative humidity are among the causes sufficient to impress a totally different character upon the range of the daily fluctuation, from that we might otherwise have expected from the meridian altitude of the sun and the length of its diurnal arc.

### DISCUSSION OF THE ANNUAL FLUCTUATION, OF THE MONTHLY AND ANNUAL EXTREMES AND OF THE SECULAR VARIATION OF THE ATMOSPHERIC TEMPERATURE

WITH

TABLES OF RESULTING TEMPERATURES FOR EACH DAY OF THE YEAR, OF OBSERVED MONTHLY EXTREMES AND OF ANNUAL MEANS FOR A SUCCESSION OF YEARS.

---

*The annual fluctuation of the temperature.*—The annual fluctuation in the temperature of the lower atmosphere is exhibited in the progression of the successive monthly means, for a great number of stations in the General Temperature—Tables of Section I, but it may also be shown by the tabulation of the mean temperature, derived from a series of years, of every day of the year. The latter method, while more advantageous, is also more laborious than the first, but is indispensable in inquiries respecting certain suspected irregularities in the annual fluctuation.

In the application of Bessel's periodic function to the case of the annual fluctuation of the temperature as derived from the *monthly means*, corrections are required for the inequality in the *length* of the calendar months, and for *curvature* or difference in the *mean* monthly temperature, and the temperature for the *middle* of the month. The first correction, for unequal length, affects principally the mean annual temperature, and but slightly the periodic terms in the epochs; the second correction, for curvature, affects only the amplitude of the fluctuations. These corrections may be applied separately and for each month before the application of the periodic function, especially in the case where the temperature for each day is known. When we have to make many applications of the formula, it becomes desirable to reduce this labor as far as is possible, without sacrifice of accuracy. There is no need for introducing these small corrections to results from short series, and it suffices to state the rules for complete quadriennia, in which, consequently, the mean length of February equals 28.25 days, and the year 365.24 days nearly; the average or normal month comprises 30.44 days nearly.

The mean temperature for the months of normal length may readily be computed by means of the following epochs of the ending of each month—

|                |           |           |      |        |      |          |            |        |

|                | November  | “ “       | 0.56 | “ “    | 1st  | “        | December.  |        |
|                | December  | “ “       |      | “      | with | midnight | of the     | 31st.  |

To make use of these expressions we require to know the mean temperature of certain days near the beginning of each month; this may either be taken directly from the observations or may be computed from the monthly means. In Silliman's Journal of Science and Arts, May numbers of 1866 and of 1867, Mr. E. L. De Forest has presented the case in a different and very convenient form<sup>1</sup> by using the monthly means already computed and finding corrections thereto, employing the means of the months preceding and following. Practically the results by the two methods are identical. The general effect of the correction for inequality is to increase the annual means by a small fraction of a degree.

To exhibit the magnitude of the monthly corrections, the results for the New Haven series, extending over nearly 86 years, may serve as a sample. The second column contains the uncorrected or calendar means, the third and fourth the correction to reduce to months of mean length, according to first and second methods, the last column gives the corrected means.

<sup>1</sup> On page 316 of Sill. Journ., No. 129 (May, 1867), we find the expressions for the normal months,  $M$ , by means of the calendar months,  $m$ , as follows:—

$$\begin{aligned}
 M_1 &= m_1 + .0037 m_1 + .0030 m_{12} - .0067 m_2 \\
 M_2 &= m_2 - .0127 m_2 - .0031 m_1 + .0158 m_3 \\
 M_3 &= m_3 + .0028 m_3 - .0249 m_2 + .0221 m_4 \\
 M_4 &= m_4 - .0042 m_4 - .0200 m_3 + .0242 m_5 \\
 M_5 &= m_5 + .0016 m_5 - .0218 m_4 + .0202 m_6 \\
 M_6 &= m_6 - .0039 m_6 - .0180 m_5 + .0219 m_7 \\
 M_7 &= m_7 + .0026 m_7 - .0200 m_6 + .0174 m_8 \\
 M_8 &= m_8 + .0025 m_8 - .0103 m_7 + .0078 m_9 \\
 M_9 &= m_9 - .0027 m_9 - .0067 m_8 + .0094 m_{10} \\
 M_{10} &= m_{10} + .0030 m_{10} - .0085 m_9 + .0055 m_{11} \\
 M_{11} &= m_{11} - .0026 m_{11} - .0046 m_{10} + .0072 m_{12} \\
 M_{12} &= m_{12} + .0032 m_{12} - .0064 m_{11} + .0032 m_1
 \end{aligned}$$

Mr. De Forest also remarks that the term  $T = A + B_1 \sin(\theta + C_1)$  obtained on the supposition of calendar months will be very nearly corrected, for temperate climates, for the inequality of months by taking  $T = A + .0041 B_1 + B_1 \sin(\theta + C_1 + 46')$ . The effect on the periodical terms involving multiples of  $\theta$  is small and variable. They are preferred in the form  $\pm A_n \sin n(\theta - e_n)$ , as determined by  $\sin(n\theta + E_n) = \sin n(\theta - \frac{1}{n}(360^\circ - E_n))$  or  $-\sin n(\theta - \frac{1}{n}(180 - E_n))$  according to  $E_n >$  or  $<$  than  $180^\circ$ , the arc  $e_n$  indicates the position of the first intersection, and the ascending or descending wave is shown by the sign of the term. In the usual form the signs are all positive.

| Corrected mean          |                       |             |       |              |           | 49.095                |             |        |              |

The monthly corrections, beginning with January and continuing in regular progression, for two extreme cases are given below, viz., for Key West, Flo., with an annual range of about 14°.7, for New Haven, Conn., with about 46°.7 and for Fort Snelling, Minn., with about 61°.8.

|               |      |      |      |      |      |      |      |      |      |      |      |      |
|---------------|------|------|------|------|------|------|------|------|------|------|------|------|
| Key West      | °.00 | °.04 | °.11 | °.14 | °.13 | °.09 | °.02 | °.01 | °.04 | °.05 | °.04 | °.03 |
| New Haven     | °.00 | °.12 | °.44 | °.46 | °.42 | °.28 | °.07 | °.07 | °.17 | °.16 | °.12 | °.08 |
| Fort Snelling | °.00 | °.21 | °.67 | °.63 | °.47 | °.28 | °.04 | °.12 | °.19 | °.19 | °.18 | °.11 |

Expressed in parts of the half of the annual range or nearly as a multiplier of  $B_1$ , the correction to the mean temperature of the year derived from the mean temperature of the calendar months, in order to obtain the true mean derived from the daily means, has been determined for a number of stations as follows:—

| Locality.               | Approx. Value of Half Range. | Factor. |
|-------------------------|------------------------------|---------|
| Fort Snelling, Min.     | 30°.9 Fah.                   | 0.0043  |
| Brunswick, Me.          | 24.2                         | 41      |
| St. Louis, Mo.          | 24.1                         | 38      |
| Fort Laramie, Wyo.      | 23.7                         | 37      |
| Albion Mines, Nov. Sco. | 23.6                         | 50      |
| New Haven, Conn.        | 23.3                         | 44      |
| Toronto, Can.           | 22.8                         | 45      |
| Providence, R. I.       | 22.6                         | 44      |
| Marietta, Ohio          | 21.4                         | 43      |
| Austin, Tex.            | 16.0                         | 34      |
| Charleston, S. C.       | 15.9                         | 34      |
| Sitka, Alas.            | 12.3                         | 39      |
| San Diego, Cal.         | 9.5                          | 36      |
| Key West, Flo.          | 7.3                          | 38      |
| San Francisco, Cal.     | 4.9                          | 23      |

The factor seems to diminish with a diminishing range, but is sufficiently constant and equal to 0.0043 for half ranges above 20°, and equal to 0.0036 for half ranges below 20°. The San Francisco value is known to be exceptional.

The effect or correction to the epochal angles,  $C_1$   $C_2$   $C_3$ , may be seen from the following selected expressions of typical stations:—

| Station.            | Extent of Series in Years. | Calendar or Mean Mo. | $A$    | $B_1$  | $B_2$ | $B_3$ | $C_1$   | $C_2$  | $C_3$  |
|---------------------|----------------------------|----------------------|--------|--------|-------|-------|---------|--------|--------|
| Fort Snelling, Min. | 42                         | Cal.                 | 44°.52 | 30°.03 | 1°.60 | 0°.65 | 238°58' | 208°.8 | 184°.4 |
|                     |                            | Mean                 | 44.65  | 30.03  | 1.71  | 0.69  | 239 46  | 209.4  | 182.7  |
| New Haven, Conn.    | 86                         | Cal.                 | 49.00  | 22.66  | 0.27  | 0.39  | 233 37  | 298.0  | 139.4  |
|                     |                            | Mean                 | 49.10  | 22.66  | 0.26  | 0.41  | 234 25  | 283.2  | 140.2  |
| Marietta, Ohio      | 49                         | Cal.                 | 52.24  | 21.16  | 0.79  | 0.41  | 238 38  | 284.1  | 72.6   |
|                     |                            | Mean                 | 52.33  | 21.16  | 0.80  | 0.42  | 239 25  | 279.7  | 77.6   |
| San Diego, Cal.     | 20                         | Cal.                 | 62.11  | 8.78   | 1.59  | 0.17  | 224 07  | 285.7  | 156.7  |
|                     |                            | Mean                 | 62.14  | 8.78   | 1.58  | 0.19  | 224 50  | 285.8  | 161.7  |
| Key West, Flo.      | 26                         | Cal.                 | 77.05  | 7.23   | 0.29  | 0.20  | 228 49  | 235.7  | 243.6  |
|                     |                            | Mean                 | 77.08  | 7.23   | 0.31  | 0.19  | 229 34  | 233.0  | 243.2  |

<sup>1</sup> Uncorrected for daily fluctuation.

The terms in  $B_4$  and  $B_5$  are of no practical consequence in the present inquiry. The difference in the angle  $C_1$  for calendar and mean months is for Fort Snelling, Min., + 48'; for New Haven, Conn., + 48'; for Marietta, Ohio, + 47'; also (Sill. Journ., May, 1866, p. 377-378) for St. Paul, Min.; New York; and Charleston, S. C., + 46', and for San Diego, Cal. + 43'; for Key West, Flo., + 45'. We can therefore correct our expressions derived from the calendar months, for their inequality in length, by *substituting* for stations having a range between the hottest and coldest months exceeding 40°,

$$A + 0.0043 B_1 \text{ for } A \text{ and } C_1 + 47' \text{ for } C_1,$$

and for stations having a less range,

$$A + 0.0036 B_1 \text{ for } A \text{ and } C_1 + 45' \text{ for } C_1.$$

The effect on  $C_2$  and  $C_3$  appears irregular, and may therefore be omitted as of little importance; the values of  $B_2$  and  $B_3$  are not sensibly affected.

The preceding five expressions for the annual fluctuation refer to the middle of December for their epoch; hence, in order to count the angle  $\theta$  from the *first day of January*, we must increase  $C_1$  by 15°,  $C_2$  by twice 15°, and  $C_3$  by thrice 15°.

The second correction is nearly zero in April and May, and again in Oct. and Nov., and reaches a maximum (a few tenths of a degree) in July or August, and again in January or February, the monthly amounts changing gradually, with opposite sign for the half year when the temperature is above, and the half year when it is below the mean. Since the mean monthly temperature is numerically less than the temperature corresponding to the middle of the month, the parameters of the fluctuations must be increased, and the correction for curvature is effected<sup>1</sup> by multiplying the parameters or values,  $B_1 B_2 B_3 \dots$ , as found without regard to this, by the factors,

$$\frac{\pi}{12}, \quad \frac{2\pi}{12}, \quad \frac{3\pi}{12} \quad \dots \text{ respectively. To allow, there-}$$

$$\sin \frac{\pi}{12}, \quad \sin \frac{2\pi}{12}, \quad \sin \frac{3\pi}{12}$$

fore, for curvature, we increase the co-efficients  $B_1 B_2 B_3 \dots$  as ordinarily obtained

<sup>1</sup> A. Bravais in "Voyages en Scandinavie, etc." Pendant les années 1838, 1839, 1840. Météorologie, Vol 2, pp. 291 and 325. Paris, 18 . .

by their  $\frac{1}{8}$ ,  $\frac{1}{11}$ ,  $\frac{1}{9}$  . . . . part respectively. Inversely, if we wish to compare computed monthly means with observed means, the respective multipliers are

$$\frac{\sin \frac{\pi}{12}}{\frac{\pi}{12}}, \quad \frac{\sin \frac{2\pi}{12}}{\frac{2\pi}{12}}, \quad \frac{\sin \frac{3\pi}{12}}{\frac{3\pi}{12}} \dots$$

In the case of incomplete monthly means, one or more being wanting, the function may still be employed by first finding, by interpolation, graphical or analytical, values for the terms omitted, and obtaining first an approximate, and by a second or third (if necessary) application an exact expression for  $T$ . For the supposition of one month being omitted in the observations or  $y_0$  in the values,  $y_1 y_2 y_3 \dots y_{11}$ , wanting, Mr. Bravais gives the formula—

$$y_0 = \frac{2}{7}(y_1 + y_5 + y_7 + y_{11}) + \frac{1}{7}(y_2 - y_3 - y_4 + y_6 - y_8 - y_9 + y_{10}) + \frac{1}{7}\sqrt{3}(y_1 - y_5 - y_7 + y_{11})$$

The expressions for two or more adjacent ordinates are too complicated, and of too little use to be inserted here.

In connection with the use of the periodic function, a table giving the value of  $\theta$  for each day (noon) is herewith appended.<sup>1</sup>

<sup>1</sup> Table, as given by Mr. De Forest—

| Day. | Jan.  | Feb.   | Mar.   | Apr.   | May.    | June.   | July.   | Aug.    | Sept.   | Oct.    | Nov.    | Dec.    |
|------|-------|--------|--------|--------|---------|---------|---------|---------|---------|---------|---------|---------|
| 1    | 0°30' | 31° 3' | 58°53' | 89°26' | 119° 1' | 149°34' | 179° 8' | 209°41' | 240°15' | 269°49' | 300°22' | 329°56' |
| 2    | 1 29  | 32 2   | 59 52  | 90 26  | 120 0   | 150 33  | 180 7   | 210 40  | 241 14  | 270 48  | 301 21  | 330 55  |
| 3    | 2 28  | 33 1   | 60 51  | 91 25  | 120 59  | 151 32  | 181 6   | 211 40  | 242 13  | 271 47  | 302 20  | 331 55  |

| 30   | 29 5  | 59 38  | 87 28  | 118 1  | 147 36  | 178 9   | 207 43  | 238 16  | 268 50  | 298 24  | 328 57  | 358 31  |
| 31   | 30 4  |        | 88 27  |        | 148 35  |         | 208 42  | 239 15  |         | 299 23  |         | 359 30  |

The arc from the beginning of the year to the middle of each calendar month is found in the above table opposite the 16th for months of 31 days, and by subtracting 30', for months of 30 days; the arc to the middle of February is 44° 28'.

To exhibit the annual fluctuation in a concise form, suitable for comparisons and further deductions, a number of characteristic stations have been selected, representing various climatological features, and for which the numerical values of the several quantities entering in the expression—

$$T = A + B_1 \sin(\theta + C_1) + B_2 \sin(2\theta + C_2) + B_3 \sin(3\theta + C_3)$$

have been computed and tabulated. In preference, stations having long and reliable series of observations have been selected, and they comprise with some rough approximation to uniformity of distribution, the area of the United States, with a few representative stations in Arctic and British North America. The results are based on the monthly means presented in the general table of temperatures (Section I), they were first corrected for *daily* fluctuation<sup>1</sup> according to the hours of observation, whenever needed, those depending on 7<sub>m</sub> 2<sub>a</sub> 9<sub>a bis</sub> receiving no correction. They were next corrected for *inequality* in length of months and for *curvature*, as explained. It was deemed sufficient for the present purpose to stop at the term involving  $B_3 C_3$ , considering that this and any subsequent term represent rather local peculiarities and, moreover, are subject to considerable changes with the use of additional observations. The days of average epochs of maxima and minima were computed by the formula—

$$0 = B_1 \cos(\theta + C_1) + 2B_2 \cos(2\theta + C_2) + 3B_3 \cos(3\theta + C_3)$$

resulting from putting  $\frac{dT}{d\theta} = 0$

The 46 stations are given in five groups, each arranged according to latitude.

---

<sup>1</sup> Excepting the results for Fort Franklin, to which no corrections whatever have been applied, it is a series of less than two years. The expressions for the Arctic stations, Van Rensselaer Harbor, Port Foulke, and Port Kennedy, were taken from my discussion of the Physical Observations in the Arctic Seas by Dr. I. I. Hayes; Smithsonian Contributions to Knowledge, No. 196, Washington, June, 1867, p. 180. To these a fourth term has now been added, and the parameters have been corrected for curvature. [On p. 180  $B_1$  for Van Rensselaer Harbor should have been 35.39.]

TABLE OF COMPUTED ANNUAL FLUCTUATION  
OF THE  
TEMPERATURE OF 46 STATIONS.

## ANNUAL FLUCTUATION

[The angle  $\theta$  counts from January 1,

| <p>I Through the courtesy of Dr. E. Bessels, who had charge of the scientific observations in the Hall Polar expedition, I have received in advance of the publication, the monthly mean temperatures as observed at Polaris Bay, between Sept. 1871, and Aug. 1872, together with some other information found on the same.</p> <p>These results are given in the table below, to which I have added a reduction to refer them to months of average length, also the results computed by the formula—</p> $T = +4°.19 + 33.09 \sin(\theta + 247° 52') + 7.15 \sin(2\theta + 81°.9) + 1.83 \sin(3\theta + 51°) + 2.59 \sin(4\theta + 211°).$ <p>For the fourth term the correction for curvature <math>\frac{12}{\sin \frac{4\pi}{12}}</math> amounts to nearly <math>\frac{1}{3}</math> of <math>B_4</math>.</p> |                                               |         |                                |         |                         |        |       |         |
| <i>Polaris Bay, Hall Land.</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                                               |         |                                |         |                         |        |       |         |

d See Smithsonian Contributions to Knowledge, No. 204; Washington, June, 1867, p. 32. The expression is here corrected for curvature.

e Monthly means corrected for daily variation by one-half of the value given by the general table p. xiv.

The positions of the meteorological stations, embraced in the preceding table, are shown on the accompanying chart by dots, to which the tabular number has been attached.

If we examine the variability of the respective dates, given in the columns of "warmest day," "coldest day," and "days of mean temperature," we shall find the latter confined to the narrowest limit; near these epochs the expression for  $T$  reaches its greatest daily change and consequently fixes them with comparative accuracy, whereas near the epochs of maxima and minima the daily change is least, in consequence of which greater uncertainty must attach to these dates.

The results for the 4 Arctic stations have been united into a mean for each epoch; even these means have less weight than corresponding values at any other station, since they are based upon less than 5 years of observation. The epoch when the mean of the year is reached, with a falling temperature, is the most constant for all the stations; its dates are comprised between October 8, at Polaris Bay, and November 13, at San Francisco, both stations being of an exceptional character; all the rest cluster closely around the 22d of October, which follows 30 days after

the autumnal equinox. The average deviation from this date is 4 days, earlier or later.

The epochs of the mean value of the year, reached with rising temperature, are comprised, with the exception of Illoook which is doubtful, between April 11, at Fort Brown, Texas, and May 9, at Sitka; the average date for all other stations being April 21, which is 32 days after the vernal equinox. The average deviation from this date is 5 days, earlier or later.

The dates for the maximum temperature, with the exception of that for San Francisco which is anomalous and delayed to Sept. 23, are comprised between the limits of July 8, at Van Rensselaer Harbor, and August 15, at San Diego; all the other stations cluster about July 24, which is 33 days after the summer solstice. The average deviation from this date is  $4\frac{1}{2}$  days, earlier or later.

The dates for the minimum temperature vary between the limits of December 31, at New Orleans and at Fort Craig, and February 16, at Port Foulke; we have to except, however, the date for Van Rensselaer Harbor, which has the highly uncertain date March 1; the remainder of the stations cluster about January 18, which is 28 days after the winter solstice. The average deviation from this date is 6 days, earlier or later.

We thus see that the daily balance between the decreasing radiation and the increasing insolation at the midwinter extreme is struck earlier by 5 days than the opposite balance between the decreasing insolation and the increasing radiation at the midsummer extreme, as compared with the corresponding astronomical epochs.

Altogether, then, the curve expressive of the annual distribution of heat, for our stations, follows in epoch, on the average 31 days, or very nearly  $\frac{1}{12}$  of a year, the corresponding astronomical epochs depending on the revolution of the earth around the sun.

Examining the dates of the four epochs with respect to geographical distribution of stations within the area of the United States, we find for the 9 Atlantic coast stations, Nos. 13, 15, 19, 21, 24, 27, 30, 34, 36, the average dates: July 25, January 17, for maximum and minimum, and April 23, October 24, for an average of the year in spring and autumn. Compared with the normal epochs, viz.:—

July 24, January 18, April 21, and October 22, they appear about 1 day later than the normals. No dependence on the latitude is indicated.

The 10 centrally located stations in the valley of the Mississippi and east of the foot of the Rocky Mountains, also including two Texas stations, viz.: Nos. 37, 12, 20, 23, 26, 28, 29, 32, 33, and 35, give the respective dates:—

July 23, January 12, April 14, and October 19, which are on the average 4 days earlier than the normal values. The latitude of the stations is apparently of no consequence in this inquiry. Similarly we find for the three Pacific coast stations, Nos. 9, 39, and 46 the respective dates: August 10, January 22, May 4, and November 1, which are on the average 15 days *later* than the respective normal values, while at San Francisco the dates for the maximum and for the autumnal mean are still later. With respect to the annual thermal epochs we thus notice the apparent effect on the coast stations by the Atlantic is to retard them by about

1 day and by the Pacific for about 15 days, the later effect being necessarily the greater, owing to the prevalence of westerly winds over the whole area under consideration. In the interior, on the contrary, the epochs appear about 4 days earlier than the average values. Our data are yet too scanty to allow of any precise estimate respecting the effect of elevation on these epochs, but they appear to occur earlier for greater elevation.

The result arrived at respecting the shifting of the epochs in different longitudes may also be stated as follows: The seasons occur 5 days earlier in the valley of the Mississippi and the western plains than on the Atlantic seacoast, and 19 days earlier than on the Pacific coast.

We may arrive at a tolerably fair estimate of the annual mean temperature at any place by observing for a few days the temperature about the two epochs when the mean is reached, and still better by observing in addition about the epochs of maximum and minimum. The least labor will be spent by observing only at 8 P. M. ( $8^h 05^m$  may still improve the result), an hour which has the advantage of convenience for the observer and which produces equally good results in *all months* of the year, the values will probably keep within a half degree, during any month, and within one-tenth of a degree, for the year, of the true value.

If we now turn our attention to the annual range, we find it to vary between the limits of  $80^\circ$ , nearly, at Port Kennedy (in approximate latitude  $72^\circ$ ) and of  $10^\circ$ , nearly, at San Francisco. The next smallest annual range is attained at Key West, of about  $15^\circ$ , next follows San Diego with  $19^\circ$ , and Illoolook (approximate latitude  $54^\circ$ ) with  $20\frac{1}{2}^\circ$ . The smaller ranges are due almost entirely to the proximity and equalizing effect of the sea.

The magnitude of the annual range depends principally on the latitude and the distance from the ocean, apparently less on the altitude of the station; it is greater in the higher latitudes and appears to reach its maximum value in the region about the Great Bear and the Great Slave Lakes; from the vicinity of Lake Athabasca high values extend towards Lake Winnipeg and even within the northern boundary of the United States. Our four Arctic stations in the average latitude of  $77\frac{1}{2}^\circ$  show an average amplitude of  $70\frac{1}{2}^\circ$ , at Peel River in latitude  $67^\circ 32'$  the amplitude probably exceeds  $83^\circ$ , Fort Simpson in latitude  $62^\circ 10'$  has an annual amplitude probably greater than  $75^\circ$ , our stations Nos. 5 and 6 in the average latitude of  $62^\circ$  have an amplitude of nearly  $72\frac{1}{2}^\circ$ , Norway House in latitude  $53^\circ 50'$  shows nearly  $71^\circ$ , while at Fort Stevenson, Dakota, in latitude  $47^\circ 36'$  the observed amplitude is as high as  $72^\circ$ , and at Fort Pierre, Dakota, in latitude  $44^\circ 23'$  a range above  $70^\circ$  is indicated; these last two stations exhibit a range of a truly arctic character.

The rigor of a climate may be supposed measurable by two factors, viz.: the mean annual temperature and its range, which latter is approximated by the value  $2 B_1$  (provided  $B_2, B_3, \dots$  are small in comparison). The values of  $A$  in our table fluctuate between the extreme limits of  $-2^\circ.2$  at Van Rensselaer Harbor, and of

---

<sup>1</sup> A still greater range of about  $90^\circ$  probably occurs at Fort Yukon, Alaska, in latitude  $66^\circ 34'$ , but our observations are too limited to give an exact value.

+ 77°.1 at Key West, Florida; their geographical distribution and relations within the limits of the United States are sufficiently shown on the chart of the mean annual isothermals.

*Apparent interruptions in the regularity of the annual fluctuation.*

While, for all general purposes of comparison, monthly means will be found quite sufficient for the elucidation of the character of the annual fluctuation, they will not be adequate in the case of a special and detailed examination, having for its object to ascertain the reality of certain anomalies in the otherwise regular progression.

It has been noticed, elsewhere, that at certain stations and at certain periods of the year, the regularity of the annual march of the temperature appears interrupted for a few days by interfering with the ordinary rising or falling of the temperature, as we should expect it, at these periods of the year. The phenomenon has been attributed to local as well as to cosmical influences; it would seem to be referable to the setting in of a particular wind at these times, causing the mean temperature to be more or less influenced.

Of such periods of apparent irregularities, pointed out by different meteorologists,<sup>1</sup> the following may be mentioned: About the beginning of December and the middle of May; about the 12th of February and between the first and second week in March; it cannot be said, however, that any such periods have been fully tested or confirmed for stations in the United States, but the subject demands further research. From observations at Geneva, N. Y., Dr. Wilson<sup>2</sup> suspects an arrest of the increasing warmth during about 16 days, commencing with May 25, and a retrocession of the increasing cold in autumn from October 28th to about November 10th.

To meet the requirements of such investigations the observed temperatures have, by some, been united into 5 day means or penthemers, while others have gone through the extremely laborious process of determining the mean temperature of every day, resulting from a long series of years. Owing to the great labor of preparation but few of such tables exist, and they extend yet over too limited a period to be conclusive in their results. In places where the annual range is small, a 15 year series is quite valuable, but in our temperate and higher latitudes a combination of observations embracing at least double this time is requisite to eliminate the greater irregularities in the daily means.

There is another use of tables of daily average temperatures; by their means we can ascertain for any given day (and in combination with the known daily fluctuation, for any given hour) how much the observed temperature will be in excess or defect of the normal (or tabular) temperature belonging to that day, a

question to which an answer is often demanded in the study of the progress of certain unusually hot or cold terms or waves spreading themselves over large surfaces.

In the following series of tables of the average temperature of each day of the year, the observing hours as well as the corrections applied (if possible or necessary) to reduce to daily mean are added to each station.

| Day of Month.                                                                       | Jan.  | Feb.  | Mar.  | Apr.  | May.  | June. | July. | Aug.  | Sept. | Oct.  | Nov.  | Dec.  |

Observations at ☉ rise, noon, and 8 P. M. Means uncorrected.

Using the tables for Montreal and Amherst, the correction to mean deduced from observations at ☉ rise, noon, and 8 P. M., to refer to mean of day is very small, for 6 months it is nearly 0, and probably does not rise to 0.2 or 0.3 in any one month.

Observations at 8 A. M. Tabular numbers corrected for daily fluctuation.

To correct the table of temperatures observed at 8 A. M., for daily fluctuation, two sets of corrections were applied; first, the observed means were referred to the means from observations at 8 A. M., Noon, sunset, and 10 P. M., taken at Salem from a 10 year series between 1819 and 1828, inclusive; secondly, the means so corrected were referred to the daily mean by means of the Amherst table. The two sets of corrections and their sum are as follows:—

|          | I.    | II.   | I & II. |           | I.    | II.   | I & II. |
|----------|-------|-------|---------|-----------|-------|-------|---------|
| January  | +4.52 | -0.89 | +3.63   | July      | +2.26 | -0.96 | +1.30   |
| February | +4.48 | -0.47 | +4.01   | August    | +2.51 | -0.82 | +1.69   |
| March    | +3.52 | -0.91 | +2.61   | September | +3.49 | -1.25 | +2.24   |
| April    | +2.49 | -1.03 | +1.46   | October   | +4.54 | -1.62 | +2.92   |
| May      | +1.94 | -0.98 | +0.96   | November  | +3.57 | -1.03 | +2.54   |
| June     | +1.70 | -0.99 | +0.71   | December  | +4.16 | -0.46 | +3.70   |

The above corrections refer to the middle of each month, and by interpolation they were found for each day.

**Williamstown, Mass.** Lat. 42° 43'. Long. 73° 13' W. of G.

Alt. 721 feet. 23 years of observation; from 1816 to 1838, inclusive. Prof. C. Dewey and Prof. E. Kellogg. MS. in Smithsonian Coll.

Observing hours various, generally 0<sub>1</sub>, 1<sub>a</sub> or 2<sub>a</sub>, 10<sub>a</sub>, from Oct. to March, inclusive, and 6<sub>m</sub>, 1<sub>a</sub> or 2<sub>a</sub>, 10<sub>a</sub>, in the remaining months. The tabular quantities are corrected for daily fluctuation.

To correct the observed daily means resulting from three observations a day, taken at various hours, the following table was prepared and used:—

|           |          |      |          |      |          |      |          |      |
|-----------|----------|------|----------|------|----------|------|----------|------|

Observations at 3 P. M. for 2 years, at 9 P. M. for 10 years, and at 7 A. M., 2 and 9 P. M. for 9 years. Tabular numbers corrected for daily fluctuation.

In computing the original table, the observations at 3 P. M. were used for two of the years, those at 9 P. M. for ten, and the daily means at 7 A. M., 2 and 9 P. M. for the remaining nine. When combined they afford a tolerable approximation to the true mean, as may be seen from the following statement, which shows the correction for daily fluctuation at 2 and 9 P. M. deduced from the observations of ten years of this series, from 1820 to 1829, inclusive, and the reduction from 2 P. M. to 3 P. M. from the Mohawk table of daily fluctuation:—

|          | Corr'n at 2 P. M. | Refer'd to 3 P. M. | Corr'n at 3 P. M. | Corr'n at 9 P. M. | Corr'n to 7 <sub>m</sub> , 2 <sub>a</sub> , 9 <sub>a</sub> |           | Corr'n at 2 P. M. | Refer'd to 3 P. M. | Corr'n at 3 P. M. | Corr'n at 9 P. M. | Corr'n to 7 <sub>m</sub> , 2 <sub>a</sub> , 9 <sub>a</sub> |

| June     | -7.9              | -.5                | -8.4              | +1.8              | -0.5                                                       | December  | -3.8              | +1.1               | -3.7              | +0.7              | -0.3                                                       |

The correction to mean of 7, 2, 9 is from the Mohawk table; now twice the correction 3 P. M. + ten times that at 9 P. M. + nine times that at 7, 2, 9, divided by 21, gives the following table of corrections:—

|          |      |       |      |           |      |          |      |
|----------|------|-------|------|-----------|------|----------|------|
| January  | -0.2 | April | +0.1 | July      | 0.0  | October  | -0.1 |
| February | -0.4 | May   | -0.1 | August    | -0.1 | November | 0.0  |
| March    | -0.2 | June  | -0.1 | September | -0.1 | December | -0.1 |

These small corrections were applied, they answer to the middle of each month, and were interpolated for any other day.

| Day of Month.                                                                                      | Jan.  | Feb.  | Mar.  | Apr.  | May.  | June. | July. | Aug.  | Sept. | Oct.  | Nov.  | Dec.  |

Two observations a day;  $\odot_2$  and  $2_2$ , Nov. to April, inclusive;  $\odot_2$  and  $3_m$ , May to Oct. inclusive. Means uncorrected for daily fluctuation.

J. Cassin & Co., Boston.

The tabular numbers for five stations, having the longest series of observations, are graphically represented on the accompanying plate.

The greater irregularity for the shorter series is sufficiently well marked, and the zigzag lines of the Salem temperature, derived from a 43 year series, are yet inconveniently large for the purposes of comparison.

The Marietta and Providence daily temperatures show many coincidences in the zigzag lines or in the differences from their respective mean values and particularly so in the *winter season*; the Portland temperatures, also, frequently conform to the same fluctuations. From this we infer that changes from the normal temperatures extend, especially in the winter season, over large tracts of country, and there are also indications of the occurrence of the same phase about one day later in Rhode Island than in Ohio, showing that the normal state of the weather has a tendency (especially in the winter) to an easterly progression, the same as recognized in the case of storms or unusual thermal disturbances of the atmosphere. About the 20th of February, all stations indicate a rapid rise of temperature, this epoch, therefore, deserves further attention; there are also fainter indications of an unusual depression about May 31, of a constancy between September 13 and 18, and of a rapid decline about Nov. 26.

The temperatures recorded at the above stations refer nearly to the *same* period of time, and consequently exhibit many coincidences of departures from regularity which only belong to this period, but as soon as we compare with recorded temperatures covering *another* period, these coincidences disappear, and it is only by such comparisons of different epochs that we can assure ourselves of the reality or non-reality of any suspected deviation from the regular annual progression. The character of the Salem line is essentially different from that of any of the other lines, its period terminating about the time of the beginning of the others. This is the only station where the record extends, in part, to the past century.

Examining now, specially, the suspected periods of irregularity they will possess a strong probability of existence if exhibited alike for two independent epochs, for instance, those of the Salem and Providence series. About the beginning of December the march of temperature, at all the stations given, appears to be normal, though there is a remarkable depression about November 26, 27, 28, which latter feature seems to demand further attention. There is no thermal anomaly about the middle of May,<sup>1</sup> and the progression about February 12th and in the first and second week of March appears regular enough; at this season, however, the accidental irregularities are very great, and may hide any smaller fixed deviation. The suspected arrest of increasing temperature after May 25 is not supported by the Marietta and Salem observations, and the rise or constancy of temperature noted

---

<sup>1</sup> In an Article on the Variations of Temperature at Toronto, Canada (Phil. Trans. Roy. Soc., 1853, Vol. 143, part I), Col. Sabine remarks: "On a reference to Table IV, it is seen that on the average of the twelve years from 1841 to 1852 the 11th of May was 0°.1 *below* and on the 12th and 13th of May respectively 3°.1 and 2°.4 *above* the general mean of the temperature. The meteorological observations at Toronto during these twelve years do not, therefore, support the supposition that the depression of temperature on the 11th, 12th, and 13th of May observed at Berlin (from a series of 86 years of observations) is a general and periodically recurring phenomenon over the whole globe."

at Marietta and Providence between October 27, and November 2, is contradicted by the ordinary fall of temperature observed at Salem during this period, but appears supported by Toronto.

The smooth curves, given in the Marietta and Providence diagrams, which cut off the zigzags, equally, above and below, are obtained by the method of successive means, and in this instance represent the sixth order of means.<sup>1</sup> This process facilitates comparison and enables us to construct tables of daily temperature, the values of which have thus become more consistent by the removal of the greater accidental irregularities.

In the tables which follow, the annual fluctuation is given either directly by the daily ordinates or by those of smooth curves, obtained by the process just explained, or by means of Bessel's periodic function with constants supplied by observation, as stated at the top of each table.

The director of the Toronto observatory noticed the curious fact, that the daily means or normals of temperature made out by General Sabine for the epoch 1841 to 1852 had now become totally inapplicable, in consequence of which a new set of normals was prepared, employing the series of observations from 1859 to 1868, and calculating the table with the help of Bessel's periodic function as had been done before.

The two sets of tables given for Toronto will, therefore, represent the variability of the annual fluctuation for two epochs not very remote from those when the extreme values obtain, as has been found from a further study of this phenomenon of the shifting of the epoch of maximum cold and of apparent changes in the curve of the annual fluctuation.<sup>2</sup>

On account of this variability of the annual fluctuation, the years of observation from which the daily means were deduced, are stated at the head of each table.

<sup>1</sup> Supposing  $y_1, y_2, y_3, y_4, y_5, y_6, y_7$  to represent consecutive values of the daily temperature, the resulting mean of the sixth order and corresponding in point of time to the middle ordinate  $y_4$  will be given by

$$\frac{1}{6} \{y_1 + 6y_2 + 15y_3 + 20y_4 + 15y_5 + 6y_6 + y_7\}$$

and in general for  $n + 1$  ordinates, the co-efficients are those of the  $n$ th power of a binomial and the divisor equals their sum.

No precise rule can be given prescribing the limiting number of successive means, but as the values converge towards a constant, at first rapidly and afterwards more slowly, it will soon be found that after repeating the process a few times very little impression can be made on the results by continuing it, which sufficiently indicates that we have arrived at a practical limit. We may either compute directly by means of the formula, or we may set down *each* series of consecutive means; the latter process offers the advantage of a partial check in the regularity of progression of the numbers standing in the same horizontal line. It will also be convenient to stop at an order of an *even* number, in which case the resulting means refer, in point of time, to noon, whereas odd numbers (which may be written between the line) refer to midnight.

<sup>2</sup> Referring the reader to a subsequent part of this paper for the analyzation of the results connected with this inequality, it may be stated that it probably exists over the greater part of the United States east of the Mississippi River, and, perhaps with some modification, also in other parts of the country; allied with it, but not necessarily connected, there appears also an inequality in the amount of greatest cold and heat extending over a number of years, which, however, leaves the annual range almost undisturbed. These inequalities are necessarily of a periodic nature, and consequently our daily means, in order to become truly normals, must comprise at least one full period (or at least half a period if the curve be regular and just includes the maximum and minimum).

**New Haven, Conn.**

[Conn. Acad. vol. i, part I, 1866.]

Resulting annual fluctuation from a series of 86 years of observations between 1778 and 1865, or mean temperature of every day derived from computation by Bessel's periodic function,

$$T = 49°.11 + 22°.92 \sin(\theta + 263°.38') + 0°.29 \sin(2\theta + 345°.24') + 0°.45 \sin(3\theta + 229°.50') + 0°.02 \sin(4\theta + 150°.50') + 0°.38 \sin(5\theta + 54°.31') - 0.08 \cos 6\theta, \text{ where } \theta \text{ counts from Jan. 15.}$$

*Variability in the mean temperature of any one day, in a succession of years.*

The fact that the amount of departure of the observed temperature of any day of the year from the normal value assigned to that day from a series of years, is variable at different periods of the year may be verified at a glance by an examination of the accompanying diagram of the annual fluctuation showing the progression of the temperature from day to day. The zigzag lines or irregularities are evidently much greater in winter than in summer.

To obtain a measure of this irregularity we deduce the probable error of each normal, and thus secure the advantage of comparative numbers of the amount of this irregularity, as well as a knowledge of the degree of reliability of our normal temperatures.

Let  $n$  = number of years from which the mean temperature of any one day is deduced.

$\Delta$  = difference from this mean and any observed temperature.

$e$  = probable error of a single value observed, or the probable amount of ordinary departure from the mean or normal value.

$\epsilon$  = probable error of normal value; then, with sufficient accuracy for our purpose,

$$e = 0.845 \frac{\sum \Delta}{\sqrt{n(n-1)}} \quad \text{and} \quad \epsilon = \frac{e}{\sqrt{n}}$$

To shorten the labor, I shall here only present the values of  $e$  and  $\epsilon$  for four epochs of the annual fluctuation, and for three days in each case, viz.: for January 20, 21, 22, for April 21, 22, 23, for July 22, 23, 24, for October 21, 22, 23; epochs which correspond respectively nearly to the times of maximum cold, of average temperature, of maximum heat, and again of average temperature.

Selecting a station near the Atlantic sea-board, one on the western slope of the Alleghanians, and one near the Red River, we have the following results:—

Probable error ( $e$ ) of the mean temperature of any day about the periods of maximum cold and heat—

|                           | January. |       |      |       | July. |      |       |       |
|---------------------------|----------|-------|------|-------|-------|------|-------|-------|
|                           | 20th.    | 21st. | 22d. | Mean. | 22d.  | 23d. | 24th. | Mean. |
| Providence, R. I. . . . . | 7°.0     | 6°.1  | 7°.9 | ±7°.0 | 3°.4  | 3°.9 | 3°.2  | ±3°.5 |
| Marietta, Ohio . . . . .  | 7.0      | 6.9   | 7.2  | ±7.0  | 3.4   | 3.1  | 2.8   | ±3.1  |
| Washington, Ark. . . . .  | 9.8      | 8.0   | 7.9  | ±8.6  | 1.6   | 1.9  | 1.4   | ±1.6  |

and about the periods of average temperature—

|                           | April. |      |      |       | October. |      |      |       |
|---------------------------|--------|------|------|-------|----------|------|------|-------|
|                           | 21st.  | 22d. | 23d. | Mean. | 21st.    | 22d. | 23d. | Mean. |
| Providence, R. I. . . . . | 4°.4   | 4°.2 | 3°.9 | ±4°.2 | 5°.9     | 6°.3 | 4°.7 | ±5°.6 |
| Marietta, Ohio . . . . .  | 5.7    | 5.8  | 6.6  | ±6.0  | 6.2      | 6.4  | 5.3  | ±6.0  |
| Washington, Ark. . . . .  | 5.2    | 4.6  | 5.2  | ±5.0  | 5.2      | 5.5  | 7.0  | ±5.9  |

We have also the probable error ( $\epsilon$ ) of our daily normals as given in the preceding tables for Providence (from a series of 28½ years), for Marietta (from a series of 32 years), and for Washington, Ark. (from a series of 20 years).

|                         | Providence. | Marietta. | Washington, Ark. |
|-------------------------|-------------|-----------|------------------|
| January 20-22 . . . . . | ±1°.3       | ±1°.2     | ±1°.9            |
| April 21-23 . . . . .   | ±0.8        | ±1.0      | ±1.1             |
| July 22-24 . . . . .    | ±0.6        | ±0.5      | ±0.4             |
| October 21-23 . . . . . | ±1.0        | ±1.0      | ±1.3             |

In midwinter the mean temperature of any day will, therefore, fluctuate, in different years, from 2 to 5 times as much as in midsummer, and the fluctuation for days in that part of the year where its mean temperature is reached, are intermediate between the maxima and minima values.

In our annual curve of the temperature at Providence, the daily means for any two adjacent days in midwinter, will, therefore, ordinarily differ by  $\epsilon \sqrt{2}$  or by  $\pm 1^\circ.8$ , and in midsummer by  $\pm 0^\circ.8$ , and at the intermediate times by  $\pm 1^\circ.3$ , and *may* differ by three times these amounts, or even more, before positively indicating any abnormal influence in the annual fluctuation. In a series of observations comprehending 100 years, the probable error of the resulting average temperature of any day, in the colder half of the year, would still be  $\pm 0^\circ.6$ , and in the warmer half  $\pm 0^\circ.4$ , and on the average, the normals for two consecutive days will differ  $\pm 0^\circ.7$ , thus showing the difficulty of clearly making out small deviations at certain suspected periods of the year. If a series of observations can be had long enough to be divided into two or more parts, and the same apparent

deviations are noted in each, the probability of their being real and not accidental would be much strengthened.

At Providence, for any day in the winter, a deviation of 20° (or of three times the probable error [e] assigned), either in excess or defect of the normal temperature of that day, is a limit which is but rarely surpassed, and for any day in summer this limit becomes 10°. At Washington, Arkansas, these limits must be changed to 25° in winter, and to 6° in summer.

As a specimen of a table exhibiting the extreme heat and cold experienced, during a number of years, on the same calendar day, the following table is given from Dr. Wilson's paper, 20th Annual Report of the Regents of the University, State of New York (Albany), for 1868.

| Day of Month.                                                          | Jan. | Feb. | Mar. | Apr. | May. | June. | July. | Aug. | Sept. | Oct. | Nov. | Dec. |
|------------------------------------------------------------------------|------|------|------|------|------|-------|-------|------|-------|------|------|------|
| <b>Geneva, New York.</b> Lat. 42° 52'. Long. 77° 02' W. of G.          |      |      |      |      |      |       |       |      |       |      |      |      |
| Alt. 567 feet. From 12 years of observations; 1854 to 1865, inclusive. |      |      |      |      |      |       |       |      |       |      |      |      |
| 1                                                                      | 51°  | 5°   | 50°  | -2°  | 53°  | 13°   | 61°   | 11°  | 69°   | 39°  | 75°  | 46°  |

*Inequality in the epoch of the annual fluctuation of the temperature.*

A secular inequality in the law of the annual distribution of the temperature has lately been noticed by Mr. Kingston, director of the Toronto observatory, who stated that about the end of 1868, it was noticed that the normals given in General Sabine's paper (Phil. Trans. vol. 143, 1853), derived from 12 years of observations at Toronto, between 1841 and 1852, were wholly inapplicable to observations of recent years, and that a new set of normals had been prepared in consequence, using the records for ten years between 1859 and 1868 and Bessel's interpolation formula.

He further communicated two tables,<sup>1</sup> showing by five-year means that January was warmer than February in 1841-5, and has since become gradually colder, and that by forming two groups of years, whose centres were distant about 20 years, the temperature of winter and spring (1841-50) had now (1861-8) become lower, and the temperature of summer and autumn higher, and suggests an examination of the larger series of places in the United States with a view of learning whether the progressive change is general or confined to special localities.

In taking up the study of this subject the existence of such an inequality was confirmed for a number of places, and its geographical range and epochs were approximately determined. Selecting, from our general tables of monthly temperatures, such stations as appeared to me best suited for the purpose, on account of their location and length of record, the differences (J.—F.) of the monthly means of January and February, as well as the differences (J.—A.) of the monthly means of July and August, were formed for each year, and the results were united into means of five years:—

Table of differences (J.—F.): a + sign indicates February colder than January, a—sign the reverse.

<sup>1</sup> Comparison of means of Jan. and Feb. in groups of five years, from observations at Toronto:—

|                                    |                                    |
|------------------------------------|------------------------------------|
| 1841-45 Jan. warmer than Feb. 2° 6 | 1856-60 Jan. colder than Feb. 0° 3 |
| 1846-50 " " " " 2.6                | 1861-65 " " " " 1.5                |
| 1851-55 " " " " 0.9                | 1866-69 " " " " 2.1                |

Comparison of seasons in two groups of years:—

|                      | Winter. | Spring. | Summer. | Autumn. |
|----------------------|---------|---------|---------|---------|
| 1841-50 . . . . .    | 25° 1   | 41° 0   | 64° 7   | 46° 4   |
| 1861-68 . . . . .    | 23.4    | 40.3    | 65.6    | 47.4    |
| Difference . . . . . | -1.7    | -0.7    | +0.9    | +1.0    |

In General Sabine's paper, the coldest day is Feb. 14, the warmest July 28.

In 1849-68 " " " " Jan. 6, " " " 22.

(Letter to the Secretary of the Smithsonian Institution of Jan. 25, 1870.)

In a few instances the means are derived only from 3 or 4 years, and to complete the table means from a station adjacent to that heading the column were introduced; upon the whole, the table required the use of monthly records for an aggregate of 540 years. Notwithstanding the incidental irregularities in the successive values of this table, they appear to point conclusively to an epoch between 1841 and 1850 when the positive values reached a maximum, in other words, when the mean temperature of February was the lower (or when the lowest temperature of the year fell in that month). They also indicate, though with less certainty, a preceding epoch about the beginning of the century, when the coldest epoch of the year fell early in January, in which month it is again found at the present time. Such a shifting in the epoch of greatest annual cold can only be of a periodic nature, and we may, therefore, look forward in the course of a few years to a return motion.

To elucidate the point, whether the epoch of maximum annual heat was accompanied by a corresponding movement, a similar table was prepared containing the differences (*J.—A.*), a + sign indicating July warmer than August, a — sign would indicate the reverse. The successive annual values of which this table is made up were found to be much more irregular than the corresponding values for the cold period, though the individual differences are *smaller*, a fact which might have been anticipated from our knowledge of the greater variability of temperature in winter when compared with that of summer. The parallelism of the movement over large areas, also, is less distinctly pronounced in summer than in winter.

Table of differences (*J.—A.*) for supposed change in epoch of the greatest annual heat.

There appears to be no regular progression in any of the figures of this table that could be ascribed as accompanying the singular anomaly of values between 1841-50, and even when means are taken for each five-year combination, the result remains inconclusive. If there is any variation in the epoch of maximum heat, it

must be confined within much narrower limits than the variation in the epoch of maximum cold.

On the western coast the records of three stations were examined (San Diego, San Francisco, and Sitka), but, owing to the shortness of the record, only a glimpse of the existence of an inequality could be obtained with an indication of the occurrence of the extreme shift in winter later than in 1844.

Taking means of the values for the different stations, for winter and summer, we obtain the following results:—

| Epochs.   | Cold Season.     |                   | Warm Season.     |                   | Epochs. | Cold Season.     |                   | Warm Season.     |                   |

| 1826-30   | 6                | -3.0              | 8                | +1.8              |         |                  |                   |                  |                   |

Extreme values are indicated by being contained within brackets, and they point approximately to the epochs 1809 and 1844, when the greatest cold fell on the average early in January and about the middle of February, respectively. Respecting the epoch of greatest heat, the figures leave us in no doubt, though the probability would seem to be in favor of a *corresponding* lateness about 1808 and an earlier occurrence in the position of the maximum at some rather undefined later epoch.

If the preceding result could be considered as well established, the cycle of the shifting of these dates of maximum cold (and heat) would be about twice 35 years.

*Tables of observed extremes of temperature, for every month, for a series of years.*

To complete our information respecting the annual fluctuation of the temperature, it is necessary to examine the extreme variations from the normal values; with this view the following table of monthly extremes has been prepared for a number of selected stations. They comprise nearly all the longer series, for which maxima and minima have been tabulated; the extreme values given are those found in the record, entered at the regular hours of observation, as adopted by the respective observers, the cases of maxima and minima thermometers being very restricted. They do not, therefore, exhibit the absolute extremes, but only approximations to them; besides, the intervals of time over which the series extend are far too restricted to entitle the extremes to be regarded as anything more than approximations. For the geographical position, and the actual duration of each series, after the deduction of breaks, the reader will have to consult the

general tables of mean temperatures, given in Section I. Observations of a later date than 1870 are included in our table.

The tabular values are taken from a large manuscript collection, which embraces the observed monthly extremes for every year separately; in this form the table was found far too bulky to conform to the plan of this paper, and only an abstract of the manuscript is here presented.

The headings to the table give all the explanation needed. To render it easy to refer to the general tables for any further information, the table of extremes is arranged alphabetically, by States or Territories, and the stations in each are also given in alphabetical order.

---

## TABLES OF OBSERVED EXTREMES OF TEMPERATURE

FOR EVERY MONTH, FROM A SERIES OF YEARS.

PRINCIPALLY FOR STATIONS WITHIN THE UNITED STATES.

ALL VALUES ARE EXPRESSED IN DEGREES OF THE FAHRENHEIT SCALE.

<sup>1</sup> Also in 1870.

<sup>2</sup> Also in 1857, 1858, and 1860.

<sup>3</sup> Also in 1860.

<sup>4</sup> Also in 1824, 1825, 1826, and 1830.

<sup>5</sup> Also in 1871.

Although the contents of the tables of observed extremes of temperature can readily be scanned by simple inspection, there are a few prominent features which deserve to be specially noticed.

With respect to extreme heat, perhaps the most remarkable contrast is presented in the case of Fort Simpson, in latitude  $62^{\circ} 10'$ , having a greater recorded maximum ( $104^{\circ}$ ) than even stations on the Gulf of Mexico; as for instance, New Orleans ( $100^{\circ}$ ) and Key West ( $98^{\circ}$ ). This arises on the one hand from the prolonged insolation and consequent accumulation of heat and from the dryness of the air at the northern station, and, on the other hand, mainly from the presence of a large amount of moisture at the southern stations. The difference of latitude is not less than  $37\frac{1}{2}^{\circ}$ . Of places showing high extremes in all months, Forts Fillmore and Cummings, New Mexico, are prominent examples; at these stations the heat in January rises to  $95^{\circ}$  but only to  $107^{\circ}$  in June. The former fort has an altitude of 3937 feet. Other stations of high January heat are Fort Duncan, Texas, with  $91^{\circ}$ , and Camp McDowell, Arizona, Fort McIntosh and Ringgold Barracks, Texas, with  $90^{\circ}$  each.

If we regard  $110^{\circ}$  Fah. as an exceptionally high temperature we shall find it exceeded in the following states or territories and stations, according to our limited table:—

|                          |                        |                                                             |
|--------------------------|------------------------|-------------------------------------------------------------|
| Arizona . . . .          | Fort Mojavé . . . .    | $118^{\circ}$                                               |
| California . . . .       | Fort Miller . . . .    | $121$ , also Camp Cady $118^{\circ}$ , elevation 3000 feet. |
| Dakota . . . .           | Fort Sully . . . .     | $114$                                                       |
| Idaho . . . .            | Fort Boise . . . .     | $121$                                                       |
| Indian Territory . . . . | Fort Gibson . . . .    | $116$                                                       |
| Kansas . . . .           | Fort Larned . . . .    | $115$ , elevation 1932 feet.                                |
| Montana . . . .          | Fort Shaw . . . .      | $112$ , elevation 6000 feet.                                |
| Nebraska . . . .         | Fort McPherson . . . . | $115$                                                       |
| Nevada . . . .           | Camp Halleck . . . .   | $111$ , elevation 5600 feet.                                |
| New Mexico . . . .       | Fort McRae . . . .     | $120$ , elevation 4500 feet, also                           |
|                          | Albuquerque . . . .    | $114$ , elevation 5032 feet.                                |
| Texas . . . .            | Fort Mason . . . .     | $114$ .                                                     |

These stations are all in the western part of the United States, and many of them at considerable elevations.

Exceptionally depressed heat, in *January*, we find noted at: Fort Ransom  $34^{\circ}$  and Fort Wadsworth  $40^{\circ}$  in Dakota; at New Ulm and Sibley, Minn.,  $41^{\circ}$ , and at Lunenburg, Vt., Stratford, N. H., and Fort Wrangel, Alaska, of  $42^{\circ}$ .

With respect to extreme cold its geographical distribution depends mostly on the latitude, and not like the extreme heat, as we have seen, mostly on the longitude. Outside the boundaries of the United States, we have at Van Rensselaer Harbor the lowest temperature recorded  $-66^{\circ}.4$ . At Peel River we find  $-56^{\circ}$  recorded, at Fort Simpson  $-55^{\circ}$ . The temperature sinks below that at which mercury congeals, which is  $-39^{\circ}$  Fah.  $\pm 1^{\circ}$ , in the following States and places, according to our limited table:—

|                   |                      |      |                      |                                                                                                                                                     |
|-------------------|----------------------|------|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| Colorado . . . .  | Fort Garland . . .   | -40° | elevation 8365 feet. | } The region in the vicinity of these stations is one frequently visited by the most excessive cold reached within the limits of the United States. |
| Dakota . . . .    | Fort Abercrombie . . | -40  |                      |                                                                                                                                                     |
|                   | Fort Buford . . . .  | -40  |                      |                                                                                                                                                     |
| Michigan . . . .  | Fort Brady . . . .   | -47  |                      |                                                                                                                                                     |
| Minnesota . . . . | Fort Ripley . . . .  | -44  |                      |                                                                                                                                                     |
|                   | Minneapolis . . . .  | -40  |                      |                                                                                                                                                     |
| Montana . . . .   | Camp Baker . . . .   | -53  |                      |                                                                                                                                                     |
|                   | Fort Benton . . . .  | -51  |                      |                                                                                                                                                     |
|                   | Fort Ellis . . . .   | -53  |                      |                                                                                                                                                     |
|                   | Fort Shaw . . . .    | -43  |                      |                                                                                                                                                     |
| New York . . . .  | Gouverneur . . . .   | -40  |                      |                                                                                                                                                     |
|                   | Lowville . . . .     | -40  |                      |                                                                                                                                                     |
|                   | Madison Barracks . . | -44  |                      |                                                                                                                                                     |
|                   | Sackett's Harbor . . | -46  |                      |                                                                                                                                                     |
|                   | Salem . . . .        | -40  |                      |                                                                                                                                                     |
| Wyoming . . . .   | Fort Fetterman . . . | -40  |                      |                                                                                                                                                     |
|                   | Fort Laramie . . . . | -40  |                      |                                                                                                                                                     |
|                   | Fort Sanders . . . . | -50  | elevation 7160 feet. |                                                                                                                                                     |

To the above would certainly have been added the States of Iowa, Maine, New Hampshire, Vermont, and Wisconsin, and most probably others bordering on these to the southward, but for our limited collection both in number of stations and in length of interval of time.

In the warmest month in the year, that is, for July, the temperature is recorded to have sunk to the freezing point of water (32°) or *below* it, in Arizona, Maine (at Brunswick, 27°), Michigan, Minnesota, Montana, Nevada, New York, Oregon, Washington Territory, and Wyoming.

Subtracting the lowest from the highest temperature recorded at any one station we obtain the *extreme range* of recorded variability, of which the following selected values may serve as examples: Extreme ranges at one or more stations equaling or exceeding 140°. British North America (Fort Simpson) 159°. Dakota 146°, Iowa 140°, Kansas 140°, Michigan 140°, Minnesota 147°, Montana 156°, New York 142°, Wisconsin 140°, and Wyoming 147°.

The least annual extreme range is recorded at Indian Key,<sup>1</sup> Florida, 42°, and very small ranges at Key West, Florida, 54°, at Fort Point, Golden Gate, California, 52°, and at Alcatraz Island, Harbor of San Francisco, of 53°. The ratio of the highest to the lowest range within the limits of the United States (excepting Alaska) is as 3.7 to 1.

If we investigate the extreme range for *each month separately* we find, for instance, from the 72 stations in our table for the State of New York, the average values:—

| Averages.                   | Jan. | Feb. | Mar. | Apr. | May. | June. | July. | Aug. | Sept. | Oct. | Nov. | Dec. |
|-----------------------------|------|------|------|------|------|-------|-------|------|-------|------|------|------|
| Highest temperature . . .   | 61   | 61   | 73   | 85   | 91   | 95    | 98    | 96   | 91    | 82   | 72   | 61   |
| Lowest temperature . . .    | -21  | -19  | -10  | 11   | 24   | 35    | 45    | 40   | 29    | 19   | 4    | -14  |
| Absolute monthly range . .  | 82   | 80   | 83   | 74   | 67   | 60    | 53    | 56   | 62    | 63   | 68   | 75   |
| Ratio, the average being 69 | 1.2  | 1.2  | 1.2  | 1.1  | 1.0  | 0.9   | 0.8   | 0.8  | 0.9   | 0.9  | 1.0  | 1.1  |

<sup>1</sup> A very short series.

The monthly absolute range is least in summer and greatest in winter, a result which has already been reached in a different way in reference to variations in the monthly means, and the ratios indicate a regular progression in the yearly period; the January variability in the temperature is one and a half times as great as the July variability.

The 11 stations given in the table for Florida yield the following results:—

| Averages.                     | Jan. | Feb. | Mar. | Apr. | May. | June. | July. | Aug. | Sept. | Oct. | Nov. | Dec. |
|-------------------------------|------|------|------|------|------|-------|-------|------|-------|------|------|------|
| Highest temperature . . .     | 84.2 | 85.4 | 88.0 | 90.2 | 94.1 | 97.0  | 95.7  | 97.1 | 95.5  | 90.8 | 87.2 | 85.4 |
| Lowest temperature . . .      | 30.4 | 32.4 | 39.3 | 45.9 | 55.1 | 64.1  | 68.8  | 66.7 | 63.0  | 49.1 | 40.2 | 33.0 |
| Absolute monthly range . .    | 53.8 | 53.0 | 48.7 | 44.3 | 39.0 | 32.9  | 26.9  | 30.4 | 32.5  | 41.7 | 47.0 | 52.4 |
| Ratio, the average being 41.9 | 1.3  | 1.3  | 1.2  | 1.1  | 0.9  | 0.8   | 0.6   | 0.7  | 0.8   | 1.0  | 1.1  | 1.2  |

We have the same regularity in the law of the annual progression, but the ratio of the variability in January to that of July is as 2 to 1. The average variability during the year in the latitude of New York is to the variability in the latitude of Florida as 69 to 42.

*Tabulation of the Mean Annual Temperature in the United States, and at some places in British North America, for a succession of years, from the earliest records to the close of the year 1870.*

The object of this tabulation was to furnish, in a convenient form, a basis for discussions relating to the study of the variations of our climate—as far as the same depends on temperature—during long intervals, involving questions of permanency, of periodic variations, of irregular fluctuations, and other relations. The tables will, therefore, be of permanent value, since they furnish the earliest material available, and they have consequently been made as complete as possible, at least within the area of the United States. The arrangement is that by States and Territories and by stations in each, the whole in alphabetical order.

In conformity with previous investigation the annual means have been corrected, as far as that could be done now, for daily variation, excepting those few cases where the hours of observation were unknown, as indicated by foot notes. To give to the tables the fullest extent compatible with accuracy, broken records (extending over less than one year) have been completed by interpolation, but only when observations were found recorded during at least 9 months of the calendar year. This interpolation for 1, 2, or 3 months (as the case may be) was effected as follows: comparison by differences was made with *records* complete during the period *at an adjacent station or at near places* for some months preceding and following the lacuna, and the average difference was applied to the record to furnish the interpolated value for the incomplete station. If no suitable adjacent station for comparison could be found, the general mean from the whole series for the particular months or month was substituted in the place of the blank record. The first

method of interpolation is quite perfect, the second is less satisfactory, yet it is not apprehended that the annual mean could in the worst case be vitiated or in general rendered uncertain by more than  $\pm 0^{\circ}.5$ . In all cases where such limited interpolation had to be resorted to the *fact* is indicated in the tables by an asterisk affixed.

It should also be understood that all tabular annual means were found by dividing by 12, the sum of the monthly means belonging to the *calendar months*; the small correction for inequality of months (previously referred to) is nearly *constant*, and would not affect any conclusions we may deduce from the tables; of the same nature are index errors to the thermometers and reductions for difference of elevation or different exposures of stations at no great distance apart, as for instance within the limits of a city.

The bottom line of the tables contains the resulting mean temperatures for the respective stations; they are in general the mean of all the annual means in their respective columns, but they are made up from the *separate* monthly means, and include consequently all monthly means whether they belong to complete or incomplete years, in fact we might have a resulting annual mean from observations scattered over all the months but in different years and yet no single year complete. This explains the occasional differences of the resultant temperature from the simple mean of the individual complete years, and has nothing to do with interpolation.

In conformity with custom the mean temperatures are given to two places of decimals, but the hundredths of a degree have very little real value, and that only differentially.

*Investigation of the Secular Variation.*—The following discussion, which is based upon the preceding tabular numbers,<sup>1</sup> will be limited to the examination of the secular variations of the temperature for places within the United States or for adjacent stations. To ascertain in general the character of these variations a number of stations were selected possessing the requisite length of series or from which, by proper combination from several stations at no great distance apart, such a series could be produced having as few interruptions as possible. These separate or combined series were plotted (see accompanying illustration); this could be done either by plotting directly the annual means, as in the case of New Haven (see isolated dots), or by smooth curves, as shown for all the stations which resulted from the application of the process of successive means (to the 4th order) which has been explained before. This process, while it preserves all the characteristic features of any systematic progression of temperature during a succession of years, also relieves us in a great degree from the embarrassing presence of the accidental and minor irregularities. The 4th order of means was found quite sufficient; the 8th is given for New Haven.

Further, the process of combination of the results from several adjacent stations, either for the purpose of producing a more extended series, or for filling up gaps, must be such as to preserve exactly any feature or features *common* to all the stations, whether of a progressive or a periodic character as might be produced by a disturbing influence of a general or cosmical nature. This will be done by the method of differences, as will be explained further on. If we examine any of the numerical and graphical results, for instance those for New Haven, we recognize in the first place certain apparently altogether irregular fluctuations in the annual means, their influence will be greatly reduced or destroyed by successive means and by combination of series (since they are equally liable to + and — deviations, which will tend to cancel themselves); in the second place, we notice certain systematic changes or undulations of irregular epochs and extent which will be subjected to further study with respect to their character and geographical distribution. If all the series, proposed for combination to a normal series, were of equal extent and complete, the simple mean for each year would be all that is needed, but for indirectly connected, overlapping, or defective series, the combination is more laborious, as we must take account of all possible differences or combinations,<sup>2</sup> which can only be done by application of the method of least squares. After the series have all been rendered homogeneous, by application to each of the corrections indicated with consideration of all possible combinations and their weights, the means for each year can be taken as before. A full example of the method is given below,<sup>3</sup> and the same is intended to show also the amount of local variation in the annual means after they have been reduced to a uniform series.

<sup>1</sup> The tables contain altogether about 1210 stations with an aggregate of about 8500 annual means. The general tables are estimated to represent nearly  $11\frac{1}{2}$  millions of individual observations.

<sup>2</sup> The number of combinations of  $n$  elements by twos is expressed by  $\frac{n(n-1)}{2}$ .

<sup>3</sup> Suppose it be proposed to combine to a uniform system the results of the mean annual temperature of the 49-year series at Brunswick, the 37-year series at Portland, the 31-year series at Gardiner, the 40-year series at Castine, and the 14-year series at Cornish, all in the State of Maine, for which

by having the letter *C* and a Roman numeral expressing the number of individual series attached to the name of the principal station. These combinations are as follows:—

|                     |                               |                                                                             |                    |       |                                |                    |       |

On the whole the constant reduction deduced by a rigorous method and applied to each separate series to refer to the central station, answered well enough, yet there were indications, when the several series were thus brought *side by side*, of deviations from constant reduction for some consecutive years, which imperfections may have been produced by a change of thermometer, a change in the location of the instrument, or a change of observing hours; in the latter case, it would indicate an imperfect correction for daily variation.

The character of the secular variation in the mean annual temperature, as exhibited on the accompanying plate, is that of a series of irregular waves representing a succession of warmer and colder periods, during which, however, the mean temperature deviates only about one or two degrees, in excess or defect, from its normal value. Irrespective of the minor irregularities, which have to some extent been eliminated, some of the single progressions appear quite systematic; thus, for instance, at New Haven, the temperature steadily declined from 1802 to 1817, it then increased till 1827, after which it again decreased, reaching a decided minimum in 1836. These undulations, when compared for a number of stations exposed to similar climatological conditions, approach to parallelism over large tracts of country, and exhibit considerable uniformity in their general character;

thus from Maine to Georgia these waves are of a broad and well-defined shape, as at New Haven, but they become somewhat changed in their appearance over the vast area watered by the Mississippi and its tributaries; here the undulations become more narrow and numerous, as at Fort Snelling. The change from one form into the other is very gradual, and with an increase of the geographical distances some of the old features become obliterated and new ones make their appearance. The curve for Cincinnati, for instance, partakes of an intermediate character between the eastern or Atlantic type and that of the Mississippi basin. On our western coast, as might have been expected, a new feature is developed, subject perhaps to less irregularities than in any other part of the country, and for this reason well suited for the study of the proximate causes which determine its laws. The curve for San Francisco is presented as a type for the Pacific coast.

The remarkably cold epoch about 1837 with cold years preceding and following is common to all stations represented between the Atlantic coast and the eastern flank of the Rocky Mountains, and the exceptionally warm period about 1827 perhaps extended likewise over a very large area.

There is nothing in these curves to countenance the idea of any permanent change in the climate having taken place, or being about to take place; in the last 90 years of thermometric records, the mean temperatures showing no indication whatever of a sustained rise or fall. The same conclusion was reached in the discussion of the secular change in the Rain-Fall, which appears also to have remained permanent in amount as well as in annual distribution.

The degree of parallelism of the curves is sufficiently close to warrant an additional consolidation of results for a few characteristic stations, for further study; one typical curve will be given for the Atlantic coast and another for the Mississippi valley.

The first is composed of the long series of mean annual temperatures at Brunswick, Me., Salem, Mass., New Haven, Conn., and Philadelphia, Penn., to represent during 91 years the type of the secular change for those eastern States which are situated between the Atlantic and the Alleghany Mountains. These four series are unbroken between 1807 and 1865, and for these 59 years the individual means are set down, as in the table below; to reduce those values which lie outside of these limits to uniformity, the 59 differences for each series from the mean series were formed, and the respective mean difference applied as reductions; they are, for Brunswick  $+4^{\circ}.5$ , for Salem  $+0^{\circ}.6$ , for New Haven  $-0^{\circ}.4$ , and for Philadelphia  $-4^{\circ}.7$ . After this the means were taken for each of these years, except for the years 1780, 1783, 1784, and 1785, which are covered by one series only.

*Table of consolidated mean annual temperatures at Brunswick, Salem, New Haven, and Philadelphia.*

| 1870 | ---  |      |      |      |      |      |      |      |      |        |

The use of this table for obtaining the normal annual temperature from a single year or from a few years of observation is obvious; we have only to apply the tabular quantity with its sign reversed as a correction to the mean (observed) temperature of each year

The second type-curve is made up from the stations: Fort Snelling, Minn., Muscatine, Iowa, St. Louis, Mo., Fort Leavenworth, Kan., and Fort Gibson, Indian Ter. These series have 19 years in common (1839 to 1857 inclusive), for each of which the means from the five values were set down, the observed annual temperatures for years before and after were first referred to the same mean series by the reductions  $+7^{\circ}.9$ ,  $+4^{\circ}.7$ ,  $-3^{\circ}.2$ ,  $-0^{\circ}.8$ , and  $-8^{\circ}.6$  to the stations respectively (these numbers were deduced from comparisons of each series with every other). We have the following tables:—

*Table of consolidated mean annual temperatures at Fort Snelling, Muscatine, St. Louis, Fort Leavenworth, and Fort Gibson.*

|                      | 0    | 1    | 2    | 3    | 4    | 5    | 6    | 7    | 8    | 9    |

| 1870 | ---  |        |      |      |      |      |      |      |      |        |

[This table can be used to obtain normal temperatures at places in the Mississippi valley, as explained above.]

These differences from the normal values have been thrown into curves, and are given, together with the exhibit of the relative frequency and amount of solar spots, in the bottom line of the accompanying plate; the Atlantic type-curve is shown heavy, the Mississippi type-curve dotted, and the sun-spot curve by a zigzag line, according to Prof. R. Wolf's numbers.<sup>1</sup>

The distinguishing features, as described above, of these two type-curves appear well marked, the longer waves of the Atlantic stations show:

Principal maxima in 1802 1826 1846 1865

and principal minima in 1785 1816 1836 1857

the average interval being about 22 years; the shorter waves of the interior states show:—

Principal maxima in 1827 1833 1839 1845 1854 1860

and principal minima in 1831 1836 1843 1848 1856 1867

the average interval being about 7 years. These undulations, however, are not sufficiently regular nor sufficiently distinct, being mixed with subordinate fluctuations, to serve as a basis of prediction; all that can be claimed for them is a general exponent of the character of the secular change.

*Comparison of the secular variation of the temperature with the variations in the frequency of the solar spots.*—It is evident, from the preceding statements respecting the average duration of successions of warmer and colder years, that no intimate relation appears to exist between the two phenomena—they seem to have no feature in common, the sun-spot period of about 11 years is not systematically followed by any of the temperature waves; the chief characteristic of connection, that of equality of average periods, being wanting, we necessarily have coincidence, viz., greater development of sun-spots corresponding to greater *cold*, as for the years between 1810 and 1822, as well as opposition, viz., a greater development of sun-spots during a time of increased *heat*, as for the years 1799 to 1806, and in general we have phases of the two curves presented in all possible combinations. If we consider the small difference in the radiating energy of the surface of a spot and of the unbroken surface of the sun, as well as the comparatively small collective area of

<sup>1</sup> Prof. Wolf's relative numbers of sun-spots; from *Astronomische Nachrichten*, Nos. 1978 (March, 1874) and No. 2014 (Nov. 1874), those prior to 1759 from his "Mittheilungen."

|      | 0     | 1     | 2     | 3    | 4    | 5    | 6    | 7     | 8     | 9     |

| 1850 | 64.5  | 61.9  | 52.2  | 37.7 | 19.2 | 6.9  | 4.2  | 21.6  | 59.9  | 99.4  |
| 1860 | 98.6  | 77.4  | 59.1  | 44.0 | 46.9 | 30.5 | 16.3 | 7.3   | 37.3  | 73.9  |
| 1870 | 139.1 | 111.2 | 101.7 | 66.3 |      |      |      |       |       |       |

the spotted surface as contrasted with the whole sun, the failure in the detection of any close relationship between the annual changes of spots and of terrestrial temperature (as examined by the comparatively crude process of annual means) should not be surprising, unless there should be connected with these solar disturbances some other less direct cause producing changes of radiation. Still it is very desirable to follow up the subject by further comparisons of the American results with those obtained on the Eastern Continent, and especially with results from stations in the Southern Hemisphere.<sup>1</sup>

*Comparison of the secular variation in the temperature and the rain-fall, in the United States.*—The data for the annual rain-fall are taken from p. 154 of my memoir on the Rain-Fall (Smithsonian Contributions to Knowledge, No. 222; Washington, May, 1872), from which groups I and IV have been selected as representative stations of the same climatological conditions to which the temperature types I and II refer. The fourth order of successive means are tabulated below; these proportional numbers have already been charted on p. 157 of the Rain-Fall Memoir. The average annual amount of rain deduced from the whole series is put equal to 100.

*Secular variation in the Rain-Fall, sea-coast, Maine to Virginia.*

|      | 0   | 1   | 2   | 3   | 4   | 5    | 6     | 7   | 8   | 9   |

<sup>1</sup> To mention but one case of evidence, supposed to be in favor of a correspondence of the sun-spot and temperature periods, the reader may consult: The London, Edinburgh, and Dublin Phil. Mag., vol. xlii, July to Dec. 1871. "On the approximate decennial variation of the temperature at the Observatory at the Cape of Good Hope, between the years 1841 and 1870, viewed in connection with the variation of the solar-spots." By E. J. Stone, F.R.S, Astron. Roy. at the Cape of Good Hope. Here it is believed that the same cause which leads to an excess of mean annual temperature leads equally to a dissipation of the solar spots.

On the annexed diagram, the upper pair of curves refer to stations on the Atlantic coast, the lower pair to stations in the Mississippi valley; the heavy lines represent the secular change in the temperature, the light ones that of the rain-fall. Though the connection between the changes of temperature and rain-fall is not, in detail, any way conclusive, yet in general following out the larger waves, there seems to be some ground for concluding that years with a mean temperature above the normal have a rain-fall above the normal or average amount, and years deficient in the mean temperature present also a deficiency in the rain-fall.

That this apparent law is not expressive in the minor undulations may be explained by the small number of stations contributing information to both temperature and rain-fall, and thus admitting the presence to some extent of local peculiarities; yet it cannot be overlooked that there is some similarity in the general character of the two phenomena; further comparisons, however, are desirable.

In explanation it may be remarked, that the greater the heat of the air, the greater the amount of vapor it can hold, hence the greater the capacity for precipitation as well as for evaporation.

*Comparison of the secular variation in the temperature with the average annual direction of the wind.*—The following numbers have been extracted from p. 42 of my discussion of the Meteorological Observations<sup>1</sup> at Brunswick, Maine, made by Prof. P. Cleaveland; they give the deflections in degrees, + to the north (increasing azimuth), — to the south (decreasing azimuth), from the mean assumed direction of the wind  $\varphi = 101^\circ$ , counted like azimuths from the south around by west to  $360^\circ$ .

|      | 0    | 1    | 2    | 3    | 4    | 5    | 6    | 7    | 8    | 9    |

<sup>1</sup> Smithsonian Contributions to Knowledge, No. 204; Washington, June, 1867.

The table below contains the deflections from the normal direction of the wind  $\alpha = 68^\circ$  at Marietta, Ohio, taken from p. 36 of my discussion of the Meteorological Observations<sup>1</sup> at Marietta, made by Dr. S. P. Hildreth.

|      | 0   | 1   | 2   | 3   | 4   | 5   | 6   | 7   | 8   | 9   |
|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 1830 | +18 | +11 | +11 | +20 | +20 | +13 | +14 | +21 | +19 | +2  |
| 1840 | 0   | +8  | 0   | -10 | -11 | -12 | -23 | -35 | -34 | -25 |
| 1850 | -22 | --- | -20 | -1  | +7  | --- | --- | --- | --- | --- |

† The temperature at Marietta closely follows this type.

To interpret the above diagrams correctly, the true relation between the secular change, as shown by a succession of annual means, of the direction of the wind and of the temperature, will appear with sufficient distinctness by considering the zero line or axis of abscissæ, not as a straight line but as a curve, drawn midway between the two curves; in other words, either the normal direction of the wind is imperfectly made out (through insufficiency or imperfection of observations), or the relation of the mean direction of the wind to the mean temperature of the air is not constant; I incline to the former alternative. So far as our evidence goes, for years of northerly (+) deflections of the winds, the temperature appears to be lower, and for southerly deflections higher than the normal value. This subject also demands further investigation.

Enough has been shown to make it evident that for final explanation the secular variations in the temperature, in the rain-fall, and in the direction of the wind must be studied together, and it will probably be found that the former depend directly on the latter, though, ultimately, the deflections in the resulting direction of the wind must be referred to effects of solar radiation; the discussion must take a wider range so as to include long series of records at stations representing all parts of the globe.

<sup>1</sup> Smithsonian Contributions to Knowledge, No. 120; Washington, June, 1868.

*Range of variability in the secular variation of the annual temperature.*—If we consider the deviations of the annual means from the normal temperature of the place as fortuitous, we may employ a simple formula for the mean deviation as a measure of the amount of variability, and deduce also a value for the *probable* uncertainty to which the normal temperature, or the mean of the whole series, may be liable.

Let  $\varepsilon$  = the mean deviation of any yearly value,

$\Delta$  = the difference of any annual mean from the normal temperature,

$\Sigma\Delta$  = their sum, irrespective of sign,

$n$  = number of yearly values,

then, with sufficient precision for our comparison,

$$\varepsilon = \pm 1.253 \frac{\Sigma\Delta}{n},$$

which expression supposes the positive and negative  $\Delta$ 's to balance. The probable uncertainty attaching to the mean of the series is given by

$$r_0 = \pm 0.845 \frac{\Sigma\Delta}{n\sqrt{n}}.$$

Applying these expressions to a few of our larger and systematic series, we deduce the following results:—

| Stations.                         | Normal $T$ | $n$ | $\varepsilon$      | $r_0$              | Lowest and Highest value. | Difference from normal. | Range.        |
|-----------------------------------|------------|-----|--------------------|--------------------|---------------------------|-------------------------|---------------|
| Brunswick, Me. <sup>1</sup> . . . | 43.9       | 49  | $\pm 1^{\circ}.78$ | $\pm 0^{\circ}.15$ | { 40.3<br>47.7            | { $-3.6$<br>$+3.8$      | $7^{\circ}.4$ |
| Salem, Mass. . . . .              | 48.1       | 43  | 1.48               | .15                | { 44.5<br>50.3            | { $-3.6$<br>$+2.2$      | 5.8           |
| New Bedford, Mass. . .            | 48.2       | 58  | 1.15               | .10                | { 44.9<br>50.9            | { $-3.3$<br>$+2.7$      | 6.0           |

| Marietta, Ohio . . . . .          | 52.4       | 46  | 1.24               | .12                | { 49.7<br>55.4            | { $-2.7$<br>$+3.0$      | 5.7           |
| Fort Snelling, Minn. . .          | 44.1       | 42  | 2.07               | .21                | { 41.3<br>48.3            | { $-2.8$<br>$+4.2$      | 7.0           |
| Fort Leavenworth, Kan. .          | 52.7       | 40  | 1.83               | .20                | { 48.7<br>56.6            | { $-4.0$<br>$+3.9$      | 7.9           |
| Fort Brooke, Fla. . . . .         | 71.7       | 27  | 1.21               | .16                | { 70.1<br>74.4            | { $-1.6$<br>$+2.7$      | 4.3           |

<sup>1</sup> The annual means for 1837–39–40 are omitted, as defective.

The weighted average value of the mean annual direction  $\varepsilon$  is  $\pm 1^{\circ}.44$ , hence means derived from series of 25, 50, and 100 years are uncertain by a probable amount of  $r_0 = \frac{0.6745}{\sqrt{n}} \varepsilon = \pm 0^{\circ}.19, \pm 0^{\circ}.14, \text{ and } \pm 0^{\circ}.10$  respectively. To these values any errors that may exist in the graduation of the instruments would have to be added.

*Secular variation in the annual maxima and minima, compared with the variation in the annual means.*—In conclusion of this section of the paper, it is still desirable to inquire into the changes of the maxima and minima, and to ascertain how far these partake of the character of the secular change of the mean annual temperature. For this purpose it will suffice to examine the two typical series at New Haven and Marietta. Since the minima fall generally in January and February, and the maxima in July and August, the respective mean temperatures of these months were formed and compared with the corresponding annual means. To eliminate irregularities, the fourth order means were employed and tabulated; comparing each value with the mean from the whole series, the differences were formed, a + sign indicating higher temperature, a — sign lower temperature than the mean—they are as follows:—

*New Haven series.*

|      | ½ (J. & F.)<br>4th order. | ½ (J. & A.)<br>4th order. | ⅓ (J. to D.)<br>4th order. | Differences from Mean. |               |       |        | ½ (J. & F.)<br>4th order. | ½ (J. & A.)<br>4th order. | ⅓ (J. to D.)<br>4th order. | Differences from Mean. |               |       |

Note.—Values in parenthesis are imperfect.

If we examine, by means of the successive signs of the tabular differences, whether or not a cold winter is followed by a cold summer, and whether the average temperature of the year is below or above the normal, we find, from the New Haven series, by comparisons of the signs for the cold months with those for the year, the following results: an accord, a + sign being followed by a + sign, or a — sign by a — sign, in 64 cases; and a discord, a + sign being followed by a — sign, or the reverse, in 18 cases; there are 3 indifferent cases, one of the differences being zero; in all, 85 cases. Comparing the signs of the warmest months with those of the year, we find 61 accords, 19 discords, and 5 indifferent cases; and comparing directly the coldest and warmest months there are 50 accords, 31 discords, and 4 indifferent cases. Altogether strongly favoring the conclusion that the changes which constitute the secular variation are generally exhibited in winter as well as in summer; in other words, the causes of these variations are alike, active at all seasons of the year. In the case of Marietta, we have likewise for winter and year 30 accords, 17 contradictions, and 3 neutral cases; for summer and year 32 accords, 15 contradictions, and 4 neutral cases, and for winter and summer 19 accords, 30 contradictions, and 1 neutral case. Here the evidence is somewhat weaker, probably owing to the greater number and shorter secular undulations, due to the more western position of the station.

# INDEX.

- Abbreviations used, xvi
- Annual distribution of heat, curve of, following in epoch the corresponding astronomical epoch, 181  
of temperature, secular inequality in the law of the, 199
- Annual fluctuation, apparent interruptions in the regularity of, 183  
of temperature, discussion of, 167, 169  
of the temperature, irregularity in the epoch of the, 199  
tables of, 180, 194  
derived from the monthly means, 169  
in concise form, 174
- Annual fluctuations, table of computed, 175, 176, 177, 178, 179
- Annual maxima, secular variation in the, 319
- Annual means, deviations from the normal temperature, 318  
plotting of the, 302
- Annual range in different localities, 182  
magnitude of, depending on, 182
- Annual temperature, range of variability in the secular variation of the, 318, 319, 320
- Anomaly produced by the Gulf stream's proximity at Key West, 112
- Appalachian Range, 105
- Apparent changes in the curve of the annual fluctuation, 194
- Approximations to the absolute extremes, 202
- Area of the U. S. conveniently divided into two parts, 104
- Arrangement of tables of mean temperatures, xi-xv
- Arrest of increasing temperature in May, supposed, 193
- Atlantic, effect of vicinity of, on yearly average, 105
- Atlantic sea-board, 105
- Atmospheric disturbances, eastern progression of, 193
- Authorities for geographical positions, xi, xii
- Average of hourly observations equals the daily average, 113
- Average temperature above or below the normal, 320
- Bay of San Francisco temperature, 106
- Bessel's periodic function, 153, 154, 169, 194  
interpolating formula used in preparing a new set of normals, 199
- Bessels, Dr. E., courtesy of, 176
- Bravais, Mr., formula for correction, 173
- California, Gulf of, 105  
western part, 103
- Cascade Range, 105
- Cause of extreme heat at Fort Simpson, 226
- Changes exhibited in winter as well as in summer, 320  
from the normal temperature, 193  
of temperature observed, 200
- Characteristic of deviation at Salem, 193
- Chart showing meteorological stations, 180
- Charts, difference of lines adopted, 103  
explanation of, 103  
total number of results from series plotted on the, 106
- Chesapeake Bay, high temperature, 106
- Climate, increase of meteorological stations, the best means of ascertaining the separate effects on, 104  
rigor of, 182  
solar, 104
- Climatological conditions, 310
- Cold winter followed by cold summer, 320
- Coldest and warmest period of day in San Francisco, 158, 160
- Coldest place in the U. S. in summer, 106
- Coldest region, where, 105
- Colorado River, temperature, 106
- Columbia River, temperature, 106
- Comparison of the secular variation of the temperature with the variations in the frequency of the solar spots, 314, 315  
in the temperature and the rain-fall, 315, 316  
in the temperature with the average annual direction of the wind, 316, 317
- Comparison, process to facilitate, 194  
series of temperature for the purpose of, 193
- Connection between the secular variation of temperature and rain-fall, 316
- Constant reduction, 305
- Correction tables, xiv, xv
- Corrections, 302, 303, 304, 305  
required, 169  
to the mean temperature may be derived from hourly observations at Albuquerque, N. M., 161, 162
- Cosmical nature, disturbing influence of a, 302
- Curve of the Gulf stations, 158  
of the middle latitude stations, 158
- Curves for the northern stations, 158  
smooth, 302
- Daily fluctuation, perceptible even in mid-winter in the Arctic regions, 109  
hourly observations sufficient for investigation of, 109  
small, at Key West, caused by great humidity of the air, 109  
in the Arctic regions in mid-summer, cause of being small, 109
- collection of monthly values for, the results of observations of 18 stations, 110  
collection of monthly values for tables derived from, 110  
for stations in the Mississippi valley, material wanting for, 157
- annual variation in the range of, 157  
annual variation in the range of, interpolation required, 157  
unsatisfactory results in deducing for any given time and place the, 164, 165  
combination of the results into groups, 154  
great development in Albuquerque, N. M., of, 161  
no material on hand for the study of the effect of height on, 160

- Daily range of temperature at San Francisco, 158  
 cause of diminishing of, from latitude  $40^{\circ}$  in either direction, north or south, 156  
 diminishing from latitude  $40^{\circ}$  in either direction, north or south, 156  
 minimum in December, 158
- Daily variation, dryness of the air, cause, at Albuquerque, valley of the Rio Grande, of the excessive, 109
- Dakota, northeastern, 105
- De Forest, table in connection with the use of the periodic function, 173
- Departure of the observed temperature from the normal value of that day, 197
- Departures from regularity of temperature, 193
- Depression of temperature, unusual, in May, 193
- Deviation from the regular annual progression, 193  
 limit of, at Providence, R. I., 199
- Diagram illustrating the relation of the secular variation in temperature and direction of wind, 317
- Diagram showing the connection between the secular variation in temperature and rain-fall, 316
- Difference in the mean monthly temperature, correction required, 169
- Difference of mean values in the winter season, 193
- Difference of temperature for a few selected places in New Mexico, Texas, Arizona, and California, at certain hours, 161
- Differences, application of tables of hourly, 110  
 benefit derived from tables of hourly, 110  
 of bi-hourly, hourly, and semi-hourly mean temperatures from the mean of the day, tables of, 137-152  
 signs employed in the tables of, 111
- Different methods of exhibiting the annual fluctuation of the temperature, 169
- Diurnal fluctuations, systematic comparison, 153
- Dryness of air at elevated regions, and consequence thereof, 160
- Eastern progression of atmospheric disturbances, 193  
 tendency of the normal state of weather, 193
- Effect of Gulf stream, 105
- Elevation, effect of, on temperature, 104
- Epoch of the annual fluctuation of the temperature, irregularity in the, 199  
 of occurrence of annual mean temperature shifting in different longitudes, 182  
 cause of shifting, 182  
 presenting fair estimate of annual mean temperature of a place, 182
- Equinox, 181
- Error in computing time tables of sunrise and sunset, caused by the small variation in the sun's declination, of little moment, 113
- Examination of the larger series of places in the United States desirable, 200
- Exceptionally depressed heat in January, 226
- Exceptionally warm period, 311
- Excess of exceptionally high temperatures, 226
- Excessive large daily range noticeable in the great interior basin (Fremont Basin), 161
- Explanation of charts, 103
- Explanations and remarks on the consolidated tables of resulting mean temperatures, xi-xv
- Extension of meteorological observations will reveal new features, 158
- Extreme heat at Fort Simpson, 226  
 range for each month separately investigated, 227  
 ranges of temperature, 227  
 variations of temperature from the normal values, 202
- Extremes do not take place at the hours of observation, 161  
 of daily fluctuation in December and June, 159  
 represented by diagrams, 159, 160  
 of heat and cold observed in Albany, N. Y., on the same day, 199  
 of temperature in the great interior basin of the United States, 162
- Fahrenheit's scale employed in tabulation, xii
- Florida, 105
- Fluctuation, annual and daily, compared, 110  
 apparently irregular, in the annual means, 302
- Fluctuations, corrections to be applied, 110  
 corrections when greatest and when least, 110  
 observed in certain localities are united into a mean, 158
- Freezing point of water in July, 227
- Galveston, Texas, record completed by interpolations, 158
- Geographical distribution of extreme cold, 226, 227
- Geographical positions, authorities for, xi, xii
- Gila river temperature, 106
- Graphic method, value of, 103
- Graphical representation of the tabular numbers, 193
- Greatest constancy of temperature in summer, 163  
 in winter, 163
- Greatest depression in the daily fluctuation of temperature in the Arctic regions, 156  
 in the temperate zone, 156
- Greatest heat of day, time of, in high latitudes, 156  
 time of, in low latitudes, 156
- Great lakes, influence of, on temperature, 105
- Gulf stream, effect of, 105
- Heat, accumulation of, greater in valleys than in plains, and most apparent in the summer season, 106  
 cause of accumulation of heat in valleys, 106  
 distribution of, irregular, in the western part of the U. S., 105  
 normal, in the eastern part of the U. S., 105  
 progress of waves of, 109  
 time of daily range of, 155  
 time of greatest, least, and average, of the day, 155, 156, 157  
 transfer from more southern regions, 109  
 yearly average, 155
- Heated plains of Columbia River, 106
- Heated regions along the Colorado and Gila Rivers, the lower valley of the Rio Grande, Hudson valley, St. Lawrence valley, 106
- High extremes in all months, places showing, 226
- High heat in January, 226
- Hourly observations desirable from Albuquerque, N. M., 161  
 from San Francisco, Cal., 158, 160
- Hourly temperature at Mohawk, N. Y., 162  
 at Philadelphia, Pa., 162
- Hours of observations, xii, xiii; adopted by the Meteorol. Society in Mannheim, Germany, 110; at the military posts of the U. S., 111; by the Smithsonian Institution and the U. S. Patent Office, 111; by the Royal Society, 111; difference of temperature at certain, 161; difference of result of meteor. observations obtained when taken at different, 110; improvement on, 111
- Hottest region in the U. S., 106
- Hypsometric chart, roughly constructed, 103  
 chart of the U. S., want of, seriously felt, 103  
 requirements of a good, 103
- Incomplete monthly means, correction in case of, 173
- Inequality in the epoch of the annual fluctuation of the temperature, 199  
 of the progressive march of temperature, results of examination of, 200, 201
- Insolation, increasing, 181
- Interruptions in the regularity of annual fluctuation, apparent, 183
- Investigations in the apparent interruption in the regularity of annual fluctuations attended by great labor, 183
- Irregularities, accidental and minor, 302
- Isochermals, curves referring to the winter, 104
- Isotherals, curves referring to the summer, 104
- Isothermal charts, explanation of, 103  
 how constructed, 104  
 indications reviewed, 104  
 curves, connection of, with hypsometric features, 105

- Isothermal of 44° depending on the directions of the Rocky Mountains, the Cascade range and the Sierra Nevada, 105  
 of 52° depending on the direction of the Appalachian range, 105  
 Isothermals, curve cannot abruptly come to an end, 103  
 curves for the yearly distribution more troublesome than those for either of the other charts, 103  
 curves referring to the yearly period, 104  
 not reduced to the sea-level, and reason why, 104  
  
 Joaquin valley temperature, 106  
  
 Law of the annual distribution of temperature, secular inequality in the, 199  
 Least annual extreme range, 227  
 Length of normal month, 169  
 Lewis, Dr. James, inventor of thermograph, 110  
 Local variation of annual means, 302  
  
 Magnitude of the monthly corrections, 170  
 Maxima and minima thermometers, 202  
 Maximum temperature, dates for the, 181  
 Maximum variability in summer, 163  
 in winter, 163  
 Mean annual temperature applied to measure the rigor of climate, 182  
 object of tabulation of, 228  
 tables of, 228-301  
 Mean annual temperatures, explanation of tables of, 228, 229  
 tables of consolidated, 312, 313  
 Mean daily temperature subject to less variations with respect to latitude than the daily extremes, 157  
 Mean length of February, 169  
 of the year, 169  
 Mean temperature, character of secular variation in, 310, 311  
 for each year, 302  
 for the month of normal length, to compute, 169, 170  
 Mr. E. L. de Forest's method of finding the, 170  
 of every day derived from Bessel's periodic function for New Haven, Connecticut, 196  
 for Toronto, Canada, 195  
 of the year, correction to the, 171, 172  
 epoch when reached, 180  
 tables of, for each month, season, and the year at various stations, principally in North America, 1-99  
 Mean temperatures, explanations and remarks on the consolidated tables of, xi-xv  
 Mean value of the year, epochs of, 181  
 Mean values applicable to most localities in the U. S., between latitudes 30° and 45°, and east of the Mississippi, 112  
  
 Measure of irregularities, 197  
 Meridian, 100th, 104  
 Meteorological observations at Williamstown, results communicated to Secretary Calhoun, 110  
 difference of results obtained when taken at different hours, 110  
 hours adopted at the military posts of the U. S. for, 111  
 hours adopted by the Royal Society for, 111  
 hours adopted by the Smithsonian Institution and U. S. Patent Office for, 111  
 improvement on hours for, 111  
 system established by the Surgeon-General of the U. S., 111  
 time changed, but re-established at the military posts of the U. S., 111  
 Meteorological Society, Manheim, Germany, hours adopted by, 110  
 Meteorological stations, increase of, best means of ascertaining the separate effects on the climate, 104  
 Method of ascertaining the irregular variations of temperature, 162  
 Midsummer extreme, 181  
 Midwinter extreme, 181  
 Minima, secular variation in the annual, 319  
 Minimum and maximum range of temperature in San Francisco, 158  
 Minimum temperatures, dates for the, 181  
 Minnesota, cold region, 105  
 Mississippi, stations east of the, 104  
 stations west of the, 104  
 Monthly, absolute, range, 227  
 and annual extremes, discussion of, 167, 169  
 correction, regular progression of, 171  
 means of the range of the daily fluctuation, 157  
  
 Normals, new set of, prepared, 199  
 Normals of temperature made out by General Sabine, 194  
 North Carolina, 105  
 November, rapid decline of temperature in, 193  
 Observations, times of, xii, xiii  
  
 Pacific coast, great uniformity of the distribution of temperature along, 105  
 Pacific Ocean, direct influence of, on climate of the Western States, 105  
 influence heightened by presence of cool current running south, 105  
 Period of irregularity, 193  
 Periods of apparent interruptions in the regularity of annual fluctuations, 183  
 of irregularities of different series examined, 193  
 Permanent change of climate not perceivable, 311  
  
 Probable error of an observed temperature at any hour of the day, 164  
 of the monthly mean temperature for any hour of the day at various places, 163  
 Probable variability of the monthly means of temperature, Toronto, Canada, 162, 163  
 Progression of unusual thermal disturbance, eastern, 193  
  
 Radiation, decreasing, 181  
 Rain-fall, 317  
 comparison of the secular variation in the temperature and the, 315, 316  
 remained permanent in amount and distribution, 311  
 secular variation in the, 315  
 Rainy season in Florida, 105  
 Rapid rise of temperature in February, 193  
 Ratio between the fluctuation of the mean temperature of any day in midwinter and midsummer, 198  
 Ratio of the highest to the lowest range within the limits of the United States, 227  
 Red Lake, Minnesota, low elevations, 105  
 Reduction, no precise data for such, 104  
 Regularity of annual fluctuation apparently interrupted, 183  
 Regularity of progression of the tabular numbers for Mohawk, 164  
 Regular progression in the yearly period of the monthly absolute range, 228  
 Remarkably cold epoch, 311  
 Remarks and explanations on the consolidated tables of resulting mean temperatures, xi-xv  
 Requirements of investigations of the apparent interruptions in the regularity of annual fluctuations, 183  
 fluctuation, tables of, 195, 196, 197  
 Result of examination into the suspected periods of irregularity, 193  
 Results, combination of, 302  
 of examination, if the epoch of maximum annual heat is accompanied by a corresponding movement, 201  
 of tables from the basis of the charts, 103  
 Rocky Mountains, 105, 106  
 Rules for complete quadriennia, 169  
  
 Sacramento valley temperature, 106  
 Secular inequality in the law of the annual distribution of temperature, 199  
 Secular variation in the annual maxima and minima compared with the variation in the annual means, 319  
 in mean temperature, 310  
 in the temperature, 317  
 investigation of, 302-320  
 of temperature, discussion of, 167, 169  
 of temperature, stations selected for investigation of, 302

- Self-registering instruments required, 109
- September, constancy of temperature in, 193
- Shifting of the epoch of maximum cold, 194
- Short series, irregularities of, 193
- Sierra Nevada, 105
- Solar climate, 104  
pure, apparently subverted, 105
- Solar radiation, 317
- Solar spots, variation in the frequency of, compared with the secular variation of temperature, 314, 315
- Stations, geographical distribution of, 181, 183  
increase of, best means of ascertaining the separate effects on the climate, 104
- Successive means of temperature, 302
- Sunrise and sunset, explanation of, how computed, 113  
formulae to compute, 113
- Supposed arrest of increasing temperature in May, 193
- Surgeon-General of the U. S., system of meteorological observations established by, 111
- Systematic changes, 302
- Systematic progression of temperature, 302
- Table of daily fluctuation for Albuquerque would answer for most stations situated within the great interior basin, 162
- Table of extreme heat and cold on the same day, Albany, N. Y., 199
- Tables of consolidated mean annual temperatures, 312, 313
- Tables of corrections, xiv, xv
- Tables of daily average temperatures, use of, 183
- Tables of daily temperature, enabled to construct, 194
- Tables of differences, 110
- Tables of observed extremes of temperature for every month, 202-225
- Tables of resulting mean temperatures, explanations and remarks on the consolidated, xi-xv
- Tables of resulting temperatures, 167, 169
- Tables of the average temperature of each day of the year, 184-192
- Tables of the mean annual temperature, 306, 307, 308, 309, 310
- Tabulation of mean annual temperature, object of, 228
- Temperature, accidental irregularities, 193  
causes affecting, 109  
coincidences, 193  
comparison of decrease between certain limits of the U. S. in different seasons, 103  
comparison of the average annual direction of the wind and the secular variation in the temperature, 316, 317  
comparison of the rain-fall and the secular variation in the, 315, 316  
constant in September, 193  
corrections, results of, 104  
daily fluctuation of, 107-119
- Temperature, daily variation due to the sun's altitude, 169  
decrease, connected with decrease of pressure, 104  
diagram illustrating the relation of the direction of the wind and the secular variation in, 317  
difference at elevations, different laws to this effect, 104  
distribution, different systems, 105  
effects of, proximity of Gulf stream on, 105  
effect of the cold current between coast and Gulf stream on, 105  
exceptional and remarkable distribution in the western part of California, 103  
equal, in summer in Florida, 105  
fluctuations at Portland, 193  
for the middle of the month, correction required, 169  
high winter, associated with comparatively great precipitation, 106  
hourly means of, 155  
in February, rapid rise of, 193  
interpolation required at some stations, 155  
in November, rapid decline of, 193  
in May, supposed arrest of increasing, 193  
irregularity in the epoch of the annual fluctuation of the, 199  
march of, in December apparently normal, 193  
mean, subtracted from observed temperature at any hour, 110  
no intimate connection between the solar spots and the, 314  
object of tabulation of mean annual, 228  
of freezing point of water in July, 227  
positive sign indicates a higher and a negative sign a lower, 110  
prevalence of westerly winds on, 105, 106  
rapid rise in February of, 193  
range of the Pacific and Atlantic coast considered, 106  
remarkable depression, in November, 193  
regularity in February and March of the progression of, 193  
secular variation of, compared with the variation in the frequency of solar spots, 314, 315  
signs employed in table of average differences in, 112  
summer, of the coldest place on the Pacific compared with that of the corresponding place on the Atlantic, 106  
table of average differences in, 112  
to be studied in connection with other phenomena, 317  
true distribution of, near the surface, desired, 104  
unusual depression in May of, 193  
what corrections would be required in addition to that in reducing to sea level, 104  
winter, contrast between the Atlantic and Pacific coasts, 106
- Temperature records, scarcity of regularly continued, 109
- Temperature charts, detailed explanations of, 103
- Temperatures, tables of bi-hourly, hourly, and semi-hourly mean, 121-136  
tables of consolidated mean annual, 312, 313
- Terms of hot or cold, 184
- Thermal anomaly in May, 193
- Thermograph, 109, 110
- Time of mean temperature in the Arctic regions, 157  
in the temperate regions, 157
- Time of observations, xii, xiii
- Time of sunrise in different latitudes, 113, 114, 115, 116
- Time of sunset in different latitudes, 113, 117, 118, 119
- Time when greatest cold will occur, 109
- Time when greatest heat will occur, 109
- Toronto results, cold hours are most liable to disturbances of temperature in the cold months, 163  
confirmed by those of other stations, 163  
warm hours are most liable to disturbances of temperature in the warm months, 163
- Uniformity or range in the low latitudes, 158
- United States, eastern part, 105  
western part, 105
- Variability in the mean temperature of any one day, 197  
of temperature in winter more than double that of summer, 164  
of the annual fluctuation at Toronto, 194  
of the temperature at any hour of the day from the normal value of that hour, 162

SUMMER  
**TEMPERATURE CHART OF THE UNITED STATES**  
 SHOWING THE DISTRIBUTION BY ISOTHERMAL CURVES OF THE MEAN SUMMER TEMPERATURE OF THE LOWER ATMOSPHERE

**Explanation of Tints**

|                               |  |
|-------------------------------|--|
| Area of a temperature between |  |
| Curves of                     |  |
| 56° and 68° Fah' white        |  |
| 68 - 72 " light               |  |
| 72 - 76 " middle              |  |
| 76 - 80 " dark                |  |
| 80 - 88 " darkest             |  |

N.B. Data for high mountains are at peak, shading.

MEAN TEMPERATURE OF JUNE, JULY AND AUGUST  
 SHOWN BY ISOTHERMAL CURVES FOR EVERY 4<sup>TH</sup> FROM  
 56° TO 88° FAHRENHEIT.

Constructed from materials collected and observations made for the  
 SMITHSONIAN INSTITUTION PROF JOSEPH HENRY SECRETARY  
 by CHARLES A. SCHOTT  
 Assistant U. S. Coast Survey

WASHINGTON, SEPTEMBER 1874
